The chrome miner labors under one disadvantage, however; the deposit may give out at any time. The deposits are not found in veins or leads, from the direction of which new leads can be predicted, but in isolated pockets or deposits of all sizes, some times yielding only a few pounds and sometimes many thousand tons. The miner is never sure but that the next day may find his deposit exhausted or the quality of the ore no longer profitable. The only rule that has been found—and that is a discouraging one—is that the ore is richest at the surface and decreases in value as the mine becomes deeper. The value of a mine decreases very rapidly with the depth; for, in addition to the cost of getting ore to the surface and of keeping out the water from the mine, the ore is apt to contain less chromium. It is for this reason that the Eastern mines are not worked. They are not exhausted, but the mines in this State are newer, nearer the surface and therefore richer. As the cost of grinding and decomposing the ore is the same for rich as for poor grades, the rich ore is of course more profitable; moreover, the higher the percentage in the ore the easier is its decomposition.

The general results of over 100 analyses of ore found in California may be given as follows:

Locality.	Per Cent Chrome Oxide.
Del Norte county.....	39 to 40
Napa county.....	42 to 46
Placer county.....	35 to 55
Tuolumne county.....	41 to 45
San Luis Obispo.....	33 to 60
El Dorado county.....	20

One advantage possessed by the owners of the new mines in Alameda county is their nearness to shipping points. Tunnels have been run in for short depths to take out the ore and as soon as the pocket is exhausted the tunnel is abandoned. The land in which the greater part of the chrome belt at Livermore is situated belongs to A. Mendenhall, who has a homestead entry upon it. The ore was first noticed three years ago. The right to prospect and mine is given to anyone for \$1 per ton. This includes, of course, the discovery and opening up of a mine. The price is excellent, providing you strike it—but if not you have your labor for your pains. One man opened up two tunnels and took out but seven tons of chrome in a month. Messrs.

Ditman and Tickel, the owners of the two successful mines, employ two and three men respectively, and take out from eight to fourteen tons a day from each. The haulers receive \$3 per ton. They use four-horse teams and haul from two to two and a-half tons to the load, making one round trip a day. This gives from \$6 to \$7.50 per day per team.

The following from the Livermore Herald gives some additional facts on the subject: "The Cedar mountain chrome district is of considerable extent, covering, we should judge, several hundred acres. The soil is a yellowish-red color, with occasional loam deposits, and shows the action of fire. Float serpentine and chrome rock, upon which chemical action has brought out a bright green or yellow slime, which soon fades upon exposure to the air, may be found nearly anywhere, but a few inches beneath the surface. There are very few croppings, and the quest for chrome bodies is very nearly a blind search. That there are, however, large numbers of chrome pockets scattered over the district there is no reasonable doubt, and such being the fact, that the majority will in time be unearthed is without question. There are a number of prospects which would be worked at once, should the present mine run out of ore.

Half a mile nearer Livermore than his father and brother's mine, Douglas Mendenhall has

cret canyon district, Nevada, built a fire in his forge to sharpen some tools, when a dynamite cap, which had got into the fire by means which cannot be explained, exploded. The result to Laoli is a badly scratched face and impaired eyesight, the use of his left eye for the present being lost to him.

A narrow escape from a serious accident occurred at the Zeile mine, Amador county, last week. As the water bucket full of water was being hauled up, when near the surface the rope broke. The bucket fell two feet when it struck the center brace, and lodged there. There were two men at work at the bottom of the shaft at the time, and if the bucket had not so fortunately caught on the center brace, a serious accident must have resulted.

Laying Submarine Tunnels and Tubes.

At a recent meeting of the American Institute of Mining Engineers, Richard P. Rothwell, of New York, called the attention of the institute to a device which consists of a water-tight caisson, connected by a stuffing-box with the tube to be laid, and the caisson is pushed forward with hydraulic jacks set against the end of the tube. The tube is of hard, white iron, cast in chills in segments. These segments are carried from shore through the tube itself, in

vary with the local conditions, it is evident that a tunnel of this kind could in most cases be laid at a small part of the cost of an ordinary tunnel. The iron segments may be cast at the furnace, and would, therefore, cost little more than pig-iron, and the operation of putting the segments together is simple and inexpensive. The tube would generally be lined with concrete or beton lining, which would help to load it and would protect the iron from the effect of corroding gases. White cast-iron is very slightly acted upon by sea water.

My own professional interest in this improvement was first engaged by the fact that I had devised a somewhat similar contrivance for sinking a shaft in Pennsylvania about fifteen years ago. I used a solid sinking frame of 12-inch timbers, with a bevel iron shoe on the bottom, and into this sinking-frame a number of hydraulic jacks were let, so that when the ram was down the head of the jack rose only a little above the top of the frame. The sinking-frame was pushed down, as the gravel and clay were removed, by jacking from the permanent lining of the shaft, which was also composed of 12-inch timbers. Heavy plate-iron bolted to the outside of the sinking-frame lapped over at least two timbers of the permanent lining, and being pressed tightly against these, prevented the gravel, sand, etc., from entering the shaft

between the sinking-frame and the shaft-lining.

The method of sinking was found extremely convenient; the movement of the sinking-frame was under perfect control, the parties who used it found no drawback to it, though the frame was 75 feet long over all and 12 or 13 feet wide, the shaft being intended to have four hoistways, a pumpway and a manway. When the sinking-frame had been pushed a sufficient distance down from the permanent lining, the jacks were lowered, a few at a time, and an additional timber of the lining was slipped in and formed a new base from which to push with the jacks.

From the experience in that case, as well as from the simplicity of the problem, it appears to me possible to apply this new

method of tunnel-laying without serious difficulty, and with great economy where the local conditions are favorable. And there are many cases where the question of grade, the nature of the bottom, and other conditions render the construction of a tunnel in the ordinary way impracticable or enormously expensive. This new system offers such striking advantages in such cases, as well as for laying water pipes out into lakes, that it cannot fail to interest engineers.

The profit derived by the English company from its purchase of the Drum Lummon mine, Montana, has encouraged other English capitalists to make an investment in the same vicinity. The new company is called the Empire mining company, with \$500,000 capital. It has just secured from Cotter & Hickey two mines, the Empire and Whippoorwill, not far from the Drum Lummon, paying \$60,000 for them.

At Eureka, Nevada, last week, two shifts of men were put to work to excavate a foundation in the Eureka Con. hoisting works for the new engine in course of construction, parts of which are expected to arrive from San Francisco during the next three weeks.

PREPARATIONS are in progress for working the placer deposits in the vicinity of Tascara, Nevada, by the hydraulic process.

THE owners of the low grade mines feel anything but happy over the result of the silver fight in Congress.

FIG. 2.

A NEW METHOD OF LAYING SUBMARINE TUNNELS AND TUBES.

recently discovered a chrome prospect, and after taking into partnership his cousin Oswald, of this place, begun work. A house has been built and the mine will be opened up at once.

The future of this industry may be easily outlined. The demand for the ore is practically without limit. Messrs. Pitcher and Knight will buy at \$6 a ton all marketable ore which is delivered to them, and they expect to average from 100 to 200 tons a week this coming summer. As to the extent of the deposits, nothing but careful prospecting will absolutely determine, but enough has already been seen to convince those who examined into the matter that the entire ore belt is underlaid with ore pockets, which will be discovered and opened up from time to time for many years.

Mining Accidents.

C. C. O'Connell was killed last week by a blast in the Holmes mine, Candelana, Nevada. He, with three partners, had put in three blasts in a winze on the first level, and went to the level to await their firing. One went off, and O'Connell, in opposition to the advice of his partners, went down to see why the others had not gone off. When he reached the hole the blast went off, crushing his head terribly. A jury returned a verdict to the effect that death was caused by carelessness in going to the hole without allowing sufficient time to elapse after firing the holes.

Joe Laoli, who is mining on Bassey Hill, Se-

which a track is laid as the work progresses, and the segments are bolted together in the caisson, where there is ample room to work and proper appliances for handling heavy weights. As each segment is bolted on, the jacks are set against its forward end, and when the whole ring is complete, the caisson is pushed forward by the jacks, a trench having been dredged out in front of it, or, in very loose ground, jets of water under a heavy pressure can be thrown out to loosen the ground in front of the caisson. The direction in which the caisson is pushed is completely under control, and both the caisson and the tube are loaded to the amount necessary to overcome their buoyancy.

Mr. Rothwell said: I understand that negotiations are now under way for the construction of a 16-foot tunnel of this kind across the straits of Northumberland, between Prince Edward Island and the main land, and for tunnels in several other places. One of the most interesting uses of this system is in laying water mains out into lakes. The work can be carried on without interruption from storms, etc., and when the desired distance has been reached the caisson can be converted into a filter, which can be easily cleaned from time to time.

The accompanying illustrations show the general design of this novel and ingenious method of laying tubes, both for railroad and water-work purposes. Full particulars and estimates are furnished by the patentee, Mr. H. H. Hall, No. 95 Liberty street, New York; but, without entering into these details, which necessarily

FLOOD-FLOW OF STREAMS.

Various formulæ have been devised for the flow of streams in times of floods. These empirical formulæ are, at best, but rough approximates to the true flow.

The following formula, given by Fanning, is an expression for the "recorded flood measurement of American streams" in New England and the Middle States:

$$Q = 200 M^{\frac{5}{8}}, \quad (287)$$

in which Q denotes the number of cubic feet discharge per second, and M the area of water shed in square miles.

As California is more mountainous than New England and the Middle States, and fully as subject to heavy downfall of rain in the mountainous regions, it is not improbable that the flood discharge here will exceed that indicated by formula (287). Let it hence be accepted until otherwise determined.

Ex. 119.—The water-shed of the main Sacramento river contains twenty-four thousand seven hundred and eight square miles. What will be its flood discharge per second?

$$\text{Cal.}—(24,708)^{\frac{5}{8}} \times 200 = 915647 \text{ cubic feet.}—\text{Ans.}$$

1 grain silver, 1000 fine=\$.0026936 mint value.

1 gramme gold, 1000 fine=\$.6646142 mint value.

1 gramme silver, 1000 fine=\$.0415686 mint value.

1 cubic foot air=.0806726 pounds=564.7082 gr's.

1 pound of air at 39.83°=12.387 cubic feet by volume.

1 cubic foot hydrogen=.005042 pounds=35.2743 grains.

25 cubic feet of sand=1 ton.

18 cubic feet of earth=1 ton.

17 cubic feet of clay=1 ton.

13 cubic feet of quartz, unbroken in lode=1 ton.

18 cubic feet of gravel or earth, before digging=27 cubic feet when dug.

20 cubic feet of quartz, broken (of ordinary fineness coming from the lode)=1 ton, contract measurement.

FINIS.

PREFACE.

The present work is designed as a true exposition of the principles and application of those branches of hydraulics, of which it treats.

The necessity of such a work at this time will be obvious to those who shall have compared the results deduced from the formulas of nearly all our most noted authors on hydraulics, with the results of observation. Thus, the formulas of DuBuat, Eytelwein, Girard, Prony, D'Aubuisson, Neville, Leslie, Pole, Beardmore and Hagen, enjoying the reputation of standard authors, give as by the data at hand, with respect to the flow of water in open streams of medium size, results varying from fifteen to one hundred and twenty-five per cent in excess of the observed results, and in large streams, results varying from thirty to sixty-seven per cent below those observed. These errors are radical. The defectiveness of these and other works heretofore regarded standard on this highly important branch of hydraulics, is well portrayed by the following extracts from an article in an English periodical, "Engineering" of Dec. 31, 1875, entitled "Hydraulic Experiments," viz:

"The tabulated velocities (in Neville's work, based upon DuBuat) 'though expressed in hundredths of an inch, are in reality but the wildest guesses at the actual velocities in irrigation canals of ordinary dimensions. Colonel Cantley relied upon DuBuat when 'be laid out the Ganges Canal, and found him but a rotten reed,

"for the water in every instance tore along at an unexpected velocity, and the erosion of the bed and destruction of the works followed in its wake. Du Buat then must be put upon the top shelf of the book-case, and it will be just as well when the steps are there to carry up every English work, in which the names of Branning, Girard, Bossut, Prony, Eytelwein, or D'Aubuisson are continually recurring as authorities against whom no action can be taken. In this general clearance Beardmore, Downing, Box, and almost every other hydraulic text book compiled by Englishmen, will with more or less hesitation have been shelved."

Again, "in 1880," says L. D. A. Jackson, in his Hydraulic Manual "the extensive experiments of Captain Allan Cunningham on the Ganges Canal, have substantiated the truth of Kutter's laws when applied to very large canals, and dealt the final blow to the 'velocity formulas of all the older hydraulicians.'"

In the main text of the present work it is stated that D'Arcy in 1835, and Bazin, in 1865, published formulas better adapted than any preceding for finding the flow of water in open streams and pipes of medium size; that Humphreys and Abbot published in 1861, formulas suited to the determination of flow of large streams, but not to the flow of small streams, and that the wide gap between the formulas of D'Arcy and Bazin, and those of Humphreys and Abbot were effectually closed up in 1870 by the introduction of Kutter's formula. We will now add, that this achievement with respect to hydraulic science seems to us the masterpiece of the nineteenth century. The Kutter formula applies equally well to small, medium sized and large streams. Farther experiments may perchance require it to be somewhat modified; but so far as known at present, of all the formulas deduced for like purposes, it seems the nearest approximate to perfection.

The principal tables computed by Herr Kutter, from his formula under consideration, give the coefficients of velocity in terms of metrical measures, thereby rendering their application a laborious task in the determination of the velocities themselves in terms of feet measures.

To obviate this task, Table 27 in the present work has been computed from the same formula (Kutter's) giving in terms of feet measures, the velocities of flow in open streams, differing in regimens and in slope, and varying from the size of a small ditch to that of the Mississippi River. The table is nominally for open streams, but is equally well adapted for determining the flow of water in pipes. Table 17 computed for the flow in pipes only, will, for this purpose, be found, however, still more convenient. For this table we are indebted in part to J. T. Fanning's very admirable treatise on "Water Supply Engineering," which indebtedness we hereby respectfully acknowledge. It will be noted however that we have not only considerably enlarged the original table of Mr. Fanning, but, among other things, conferred upon it a new and valuable feature—that of giving the quantity of flow in addition to the velocity. Each result set down in Tables 17 and 27, represents essentially a mean of numerous observed results: hence must necessarily coincide in practice with other results obtained under like conditions. With respect to accuracy, scope of application and ease of reference, these tables seem to meet more fully the requirements of all concerned in this branch of hydraulic engineering, than any others designed for similar purposes.

Tables 28 and 29 will be found very important auxiliaries to Table 27, in the ready determination of the flow of water in beds of different forms.

Tables, two relating to the flow of water in rectangular weirs, four to quadrant weirs, seven to the flow through rectangular orifices, and eight to the different values of the so-called "miner's inch," will also be found of no little value in practice. The simplicity of this quadrant weir, its cheapness and the assurances by Prof. Thompson of its superiority over those of different forms, induced the author of the work in hand to compute Table 4.

This form seems peculiarly well adapted to the measurement of the flow of small quantities of water; for example, from two to 20 miner's inches. This table, however, greatly exceeds these limits. The discussion of the subjects of "maximum work effected by water on issuing under pressure from pipes," and of "minimum weight and consequent minimum cost of an inverted siphon," is, so far as the author is informed, new. By the application of the principles here demonstrated, the greatest economy, the only proper limit or standard of the truly practical, is attained.

The simple plan, pursued in the preparation of the present work consists:—

1st. In demonstrating concisely the principle, or principles, involved in the subject matter, yet in a manner sufficiently ample and clear to be readily followed by the student, or by the practitioner desiring to refresh his mind, or to assure himself of the correctness of the results.

2nd. In expressing in words the simplest rule or rules corresponding to the formula or result of such demonstration.

3d. In applying the rule or rules so derived, to practical examples with full and clear explanations; or in applying the formula direct to the examples, when it is too complex to be well expressed in words.

4th. In providing tables, so far as feasible, to meet the requirements of practice.

By means of these tables and the simple rules given therewith, most of the problems likely to occur with respect to the measurement of water in motion, as through vertical openings, over weirs, in pipes, in open streams and through nozzles; with respect to the quantity of water required for various mining purposes, and for the purposes of irrigation; and with respect to the power of water as a motor, are answered direct, or readily solved by anyone familiar with common arithmetic only, as well as by the skilled engineer.

San Francisco, March 17th, 1886.

P. M. RANDALL.

*This series of articles will shortly be published in book form by Dewey & Co., Publishers of the MINING AND SCIENTIFIC PRESS, 252 Market St., S. F. Subscriptions for the book will be filled in the order in which they are received.

Plantations for Growing Railroad Ties.

Hon. R. W. Phipps, Forestry Commissioner of Ontario, in a letter from Southern Kansas to the *Toronto Globe*, says: "One railroad board here, knowing that the growing of wood, when set about in earnest, is neither a slow nor difficult task, has established in Kansas the largest artificial plantation of forest trees in North America. These railway gentlemen themselves gave out the contract for planting over a square mile of land with young saplings of the catalpa and alantus, and their president, observing the success of their experiment, and impressed with its probable excellent financial results, has had planted at his own expense, as a speculation, as much more. Both these plantations are situated near the little town of Farlington, Kan."

These plantations have been planted in sections at different dates—the trees being now respectively two, four and six years of age. At proper intervals carriage drives are left for the convenience of getting out the timber and for inspection. Those first planted are now about 25 feet in height, the last about 12. Some of the taller are 7 inches through the stem. There are in all about 3,000,000 trees in full growing vigor on these plantations. All were planted 4 feet apart each way to shade the ground, but 8 feet is the ultimate intention, which will allow three-fourths of the trees to be cut out, a thing which can well be done when they are fit for fence posts, say 7 to 9 inches through; or, if required, they can stay even longer without in juring the plantation. When rather larger it is expected the trees will give excellent railroad ties, and at their fuller growth of fifteen or twenty years they will supply very valuable timber for cabinet work and house building. Those who have only seen the original forest, with its trees growing at hap hazard here and there, little ones and big, have but a very vague idea of the large amount of wood these closely-planted groves can spare in their process of growth.

Extensive masses of young trees planted in this manner are restricted to but one method of advancement:—the endeavor to throw out masses of leaves to the light and air of the upper surface. The lower branches, hidden in shade, rapidly die and fall to the ground, and the plantation becomes a multitude of long, straight stems, full of life and vigor, but only spreading into branch and foliage at the summit. If a tree in youth he crooked it straightens itself, if thus surrounded, as it advances in height. One acre so growing will give of wood, which is all the better taken, quite a number of cords yearly till all the superfluous trees be gone. Of the 3,000,000 trees originally planted only about one-third will be allowed to come to maturity.

Need of Forest Culture.

Quite too little attention has heretofore been given to forest culture in this country, and as an evidence for prompt and more efficient action in this direction we present the following statistics relative to the timber supply of the United States. The figures are taken from the last report of the American Forestry Congress: The land area of the United States is placed at 1,856,070,400 acres; total forest area, 440,990,000 acres; total farm area, 295,650,000 acres. Of unimproved and waste lands, including "old fields," there are 1,115,430,400 acres. The census reports the consumption of 145,778,137 cords of wood and 74,000,000 bushels of charcoal for fuel in dwellings, stores, factories, steamboats and locomotives. This in a single year would clear the forests from an area of 30,000,000 acres. The census also reports that in 1880 forest fires consumed the trees on 10,274,089 acres, and there is no reason to believe that a less area will be burned over than in 1880. The census gives the amount of lumber cut in 1880 as 18,000,000,000 feet. Last year the cut had increased to 28,000,000,000 feet, which would lay bare an area of 5,600,000 acres. Altogether, it appears that the forests of the country are subject to an annual drain of 50,750,089 acres. Good authorities on the subject say that in this rapid destruction of timber the woods suitable for vehicles are very largely represented.

THE WORLD MUST MOVE.—In 1877, electric lighting by the incandescent system was declared by many to be contrary to the scientific principles. The same was said of the use of iron, and later of steel, in bridge building. The Suez canal was once denounced as a wild and foolish scheme. Less than fifty years ago educated mechanics asserted that steamships could never carry enough coal for a long ocean voyage. Leading ship-builders told us that iron ships could not swim, and when one or two floated it was said that they would not hold together permanently. Rolls for flour making were once hooted and derided. The world will not stand still for anyone.

BIGELOW AND THE PANAMA CANAL.—A recent dispatch from New York says that much curiosity is manifested by downtown financiers as to the tenor of the report to the Chamber of Commerce on the Panama Canal project, which has just been prepared by Hon. John Bigelow, who recently made the trip to the isthmus as the guest of De Lesseps. It is understood the report is an exhaustive one, and though it does not condemn the great enterprise either as an engineering or a financial undertaking, yet as an entirety it is characterized as not of a character to excite in America popular enthusiasm in its behalf.

USEFUL INFORMATION.

Canaries.

Their Value as Pets and How to Teach Them Surprising Tricks.

A pet canary in the house is a sunbeam. Always busy, never having an idle moment, and always doing something new, it enlivens the dull and encourages the slothful to industry. Young girls or wives with a long and lonely afternoon of mending before them can set the cage on the table beside the work-basket, chat to the bird, sing with it and teach it new notes as the needle is plied. Patience and continual instruction only can teach a bird tricks. Because it sometimes gives no outward sign of imitation is not to be accepted as a belief that it is not learning. It is practicing the trick in private, and not until after a perfect rehearsal will it give a public exhibition. To teach a bird to kiss hold him lightly, chatting in soothing tones till he is quiet; then kiss the bill repeatedly, soothing him with gentle talk. Kiss the bill again and again till he ceases to struggle in fear of the salute; then bestow a final one—a kiss of approbation—and release him to partake of his enjoyment. Repeat this the next day—several times a day if you wish to teach him quickly—and he soon resorts to this performance as a method of coaxing, opening and closing his bill between your lips exactly as you have done by him; so nearly as bird imitation is possible. If he picks your lips do not notice it before him. The cage of a nervous bird should never be touched without calling the tenant's attention, because being always engaged in some project, an abrupt action startles him just as it would a human being who is come upon suddenly.

To teach him to sit upon your finger, draw a chair up near the cage, hold a conference with him, and then introducing a finger between the wires near his favorite perch, hold it there, patiently reading your hook or paper meanwhile. The new object showing no disposition to harm him, he goes up cautiously for an examination. Then he picks to ascertain the material—maybe he fights it. This is a good sign. He no longer fears it. Repay him with some choice morsel and cheerful words for his courage. Try him again in the afternoon. He may go further and light on it. Possibly the trick may take several days. Be patient. Once the step is attained, vary the program by introducing the finger in other spots. He will soon light on it at any point or angle. Next try thrusting the fingers under the door. Next times fasten it open, blocking egress with the rest of the hand as one finger extends within. When he perches on it draw him forth a little way. Next tempt him to the perch outside a little, and so on. In a short time you but have to open the cage door, uplift a finger, and he is sure to fly for it, and he may be thus called to any part of the room to rest on the familiar perch.

To eat from the fingers, let him hunger several days for some favorite dainty—say a fig. Show him one; disregard his elation; do not let him have it. Spread a few seeds over the end of your finger, and offer them close by his perch, allowing him plenty of time for speculation. Soon he will snatch off a seed or two. If he utterly refuses, put him sadly away, leaving the fig where he may see it. Next day try again; he'll take one or more. That will do. Do not plague him any longer. Give him a piece of fig in the cage and leave him alone until next day. He may feel independent, being snuffed, and refuse to pick. No matter; put him away without his fig. The next day he is sure to pick all off the fingers. Praise the act and reward him. After that it is plain sailing.—*Cincinnati Enquirer*.

PROTECTION TO IRON.—Experiments made under the direction of the administration of the Dutch State railways with various paints on iron plates are reported to have proved that the red-lead paints resist atmospheric influences much better than those of brown-red and iron oxides. The red-lead paint adhered closer to the metal, and possessed greater elasticity than the others. It was also found that better results were attained if before the paints were applied the plates were pickled, instead of being merely scraped and brushed. The test plates were pickled in muriatic acid, washed with water, thoroughly dried and, while warm, carefully oiled.

Because iron and steel are peculiarly liable to corrosion when in salt water, vessels made of them require special protection. This can be given by covering the metal with some alkaline or basic substance, or the oxides of some metal electro-positive to it. Caustic lime and soda are very efficient for this purpose, and act equally well when made into a paint with oil. But their efficiency is destroyed when they cease to be caustic or when they are saturated with carbonic acid, which they absorb freely from the air. Magnesia is equally efficient, and does not absorb carbonic acid. It therefore makes as good a material for a paint as could be desired, and moreover, forms an excellent basis on which to lay an anti-fouling paint, which it protects from the galvanic action of the iron by isolating it, while it does not affect its anti-fouling qualities.

BASE-BALL MASKS.—In the case of Thayer vs. Spalding, involving the validity of a patent for base-ball masks, Judge Blodgett, of the U. S. Circuit Court, this district, without a change

of countenance, remarked that he was not certain but that any device to protect the life of a base-ball player should be declared void on the ground of public policy. The sally coming so unexpectedly was greeted with a very audible smile. The Judge held the patent valid, and granted a decree against Spalding.

HOW TO "KILL" ENGINES.—In these days of railroad strikes we frequently hear of engines being "killed" to render them useless for service. Of course, the supposition is that the damage is intended to be the slightest that can be done to effect the end in view. The ways in which it is done was recently revealed to a reporter of the *Denver Tribune* substantially as follows: The quickest and surest way is to take the throttle lever away. It is easily carried off under one's coat. It will require two days' work and \$15 in cash to replace it. The steam gauges are sometimes knocked off and the water-glass with its fittings destroyed, when the engine is "no good." Again, the eccentric links may be taken off the valve stems, when the engine is dead. The favorite way, when an engine is on the road, is to put out the fire, open the blow-off cock which you see extending out from the side of the fire box, under the cab, and let out all the water. Then the engine must be hauled to the nearest tank and filled up before she can be again fired up. In killing engines the strikers remove such of the parts as will require the longest time to replace, and very likely at the same time let the water all out of the boilers.

SOLDER FOR GLASS, PORCELAIN AND METALS.

—Glass, porcelain and other metals can be soldered, according to the Pharmaceutical Record by an alloy made as follows: Copper dust obtained by precipitation from a solution of the sulphate by means of zinc is put in a cast iron or porcelain lined mortar and mixed with strong sulphuric acid, specific gravity 1.85. From 20 to 30 or 36 parts of the dust are taken, according to the hardness desired. To the cake formed of acid and copper there is added, under constant stirring, 70 parts of mercury. When well mixed the amalgam is carefully rinsed with warm water to remove all the acid, and then set aside to cool. In 10 or 12 hours it is hard enough to scratch tin. When required for use it is to be heated so hot that when worked over and brayed in a mortar it becomes as soft as wax. In this ductile form it can be spread on any surface to which it adheres with great tenacity when it gets cold and hard. It is intended for this alloy to be used to solder such articles as will not bear a high temperature.

GOOD MEALTH.

Premature Baldness.

O. Lassar has continued his observations on the nature of premature baldness, and has further convinced himself of the communicability of at least the form associated with dandruff. When the hairs which fall off in such cases are collected, rubbed up with vaseline, and the ointment so made is rubbed among the fur of rabbits or white mice, baldness rapidly makes itself visible on the parts so treated. That this is not due to the vaseline was shown by anointing other animals with the vaseline alone, which produced no effect whatever. He considers that the disease is spread by hairdressers, who employ combs and brushes on their customers, one after another, without any regular cleansing of these articles after each time they are used. During frequent visits to the hairdressers, it can scarcely fail that brushes are used which have been shortly before dressing the hair of one affected with so common a complaint as scaly baldness. Females are less often affected with this form of baldness, because the hairdresser more frequently attends to them at their own homes, and there uses their combs and brushes. In order to prevent as far as possible the commencement of premature baldness, the hair should be cut and dressed at home, and with one's own implements, and these thoroughly clean. When it has begun, the following mode of treatment is suggested: The scalp is to be daily well soaped with tar or fluid glycerine potash soap, which is to be rubbed in for 15 minutes firmly. The head is then to be drenched with first warm water, and then gradually colder water. A two per cent corrosive sublimate lotion is next to be pretty freely applied. The head is then to be dried, and the roots of the hair are to have a one per cent solution of naphthol in spirit rubbed into them. Finally, a pomade of one and one-half to two per cent of carbolic or salicylic oil is to be used on the head. This treatment has now in many cases brought the disease not only to a stand, but the hair has been to a considerable extent restored.—*Journal of Health*.

NEED OF REST.—Dr. Holland, than whom there were few more observant and thoughtful men in modern literature, once said: "The great trouble with us is that we do not play enough." This is as true to-day as it was fifteen years ago when he uttered the quoted words. The business man of to-day does not play enough. He runs too much in a groove. He expects too much of himself. The human machine fails to respond some day suddenly,

and a learned opinion is given as to the physical cause of the men's early death. Relaxation is the tonic and lubricant of an active life, and the business men who fail to take it, simply lose time. When a man exclaims: "I can't afford to take the time from business for this or that occasional relaxing of the rigor of daily exertion," we wonder if he ever reflects that sickness and "breaking down" are very likely to take time for him. We heard a business man not long ago advise a younger one to "keep at work; stick to it through all seasons—never miss a stroke or a moment," if he would succeed. But it was bad advice. He "sticks" best to his business who is best able to stand up to its physical demands, and this bodily power is secured only by rest, absolute rest—not mere tired sleep, but the putting off of business with the coat and the taking on of change, that rests with the dressing gown. The man who carries his business to his sitting-room or his bed is simply digging his grave. "There is nothing better established," said a medical man of prominence recently, "than this—that the stirring American business man cuts short his life by fifteen or twenty years." And we have it in the testimony of statisticians, concludes the *Record-Union*, that the vital statistics of the country prove this to be true.

INSOMNIA IN THE AGED AND ITS TREATMENT.

—In opening a discussion on this subject before the late meeting of the Clinical society of New York, Dr. C. L. Dana said that he had found the information contained in the text books upon insomnia in the aged was very slight in amount. Insomnia was not frequent in the aged, but when it was present, it was sometimes very intractable. Pathologists thought it was due to anemia and malnutrition. The thickened arterial walls and the high arterial tension from the contracted kidneys, and similar states, which were found in the aged, would indicate that the blood supply to the brain was deficient. The insomnia produced by anemia was characterized by drowsiness during the daytime, the patient falling into little naps while at night he was unable to obtain any rest. This was true of the young as well as the old. If in any case we found no actual disease, it was customary to try iron and rich diet. In the speaker's experience, however, iron did not relieve the anemia of the aged so as to produce sleep. Alcohol with the food was another remedy, and many recommended hot gruel or hot milk with alcohol before going to bed. While alcohol would relieve some cases, there were others in which the insomnia was increased.

The bromide and chloral when given in enormous doses, often failed to give relief. Opium was another remedy. Dr. H. C. Wood had recommended that we make our aged people opium eaters and alcohol drinkers. The speaker had not found that opium always agreed with the aged, and in his experience, where opium had produced sleep, it was sometimes followed by such physical and mental depression as precluded its further use. He had been disappointed in bromide and chloral and considered the results of opium sometimes disastrous. He recommended good food, warm drinks at night, and small doses of codeia with cannabis indica. Valerian and lavender, hyoscyamine, lupulin sometimes were also useful drugs.

THINGS WORTH KNOWING.—A fever patient is cooled off and made more comfortable by frequent sponging with warm soda water.

A half teaspoonful of soda in half a cup of water will relieve sick headache that is caused by indigestion.

Warm mustard water should be given to one who has accidentally swallowed poison; this will cause vomiting; after that give a cup of strong coffee. That will counteract the remaining effects.

When going from a warm room out into the cold air close your mouth and breathe through your nose to prevent taking cold.

A hard cold is oftentimes cured by a cup of hot lemonade taken at bedtime, as it will produce perspiration.

Consumptive night sweats may be arrested by sponging the patient's body at night with salt and water.

Teething children may be relieved of convulsions by being immersed in a warm bath, and cold water applied to the head.

For croup or pneumonia bruise raw onions, lay on a cloth with powdered gum camphor sprinkled over it and apply to chest and lungs, and cover with hot flannel. This is a sure cure when taken in time.

RIVERS A SOURCE OF THE SPREAD OF CHOLERA.

—The *Lancet* has made up its mind that rivers have much to do with the spread of cholera. Paper-makers will be interested to know that the severity of the last cholera epidemic at Grenada has been traced to water contamination, due to a paper-mill. The rags used at this mill were washed in the stream from which Grenada City draws its water supply. The rags thus washed came from Valencia and other cholera centers. No cholera cases had occurred in Grenada up to the time when these rags were imported. Afterward the cholera spread over the province, following in every case the course of the infected stream. Only one town thus situated escaped infection, and this because its 12,000 people drank no river water.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Alameda.

CHROME.—Livermore *Herald*, April 24: The Wm. M. Mendenhall and Douglas Mendenhall chrome mine is now nearly ready for business. The new road will be finished by Saturday night, and the workmen have begun taking out ore. They have a five-foot ledge of good chrome, and if the weather permits, will begin hauling on Monday. Six men are at work at the mine and on the road. Chrome hauling was resumed, on Monday, and will be continued this week, at least, if the weather permits. Messrs. Pitcher and Knight have contracted to ship 100 tons by steamer, and are now working to fill the order.

Amador.

IMPORTANT STRIKE IN THE BIG TUNNEL.—Amador *Ledger*, April 24: It is gratifying to be able to report a notable event in connection with the tunnel operations at Middle Bar. This enterprise has been run over 3300 feet, without meeting with any ore worth speaking of. Small seams have been cut, but neither rich nor extensive enough to justify any hopes of re-imburasing the owners for the vast sums spent in making this hole in the ground. Lately the header has been in near proximity to the point immediately underneath the works of the Mammoth mine where the rich strike was made some two years ago. A noticeable change was observed in the nature of the formation passed through. The hard granite gave place to soft material mixed with slate and quartz, which encouraged the belief that a rich strike might be made at any time. Early this week almost the entire face of the tunnel entered quartz, and this quartz body contained a seam of that rich, black gold-bearing metal identical in character with that met with above. This seam is said to be two feet wide in the floor of the tunnel, and extends above and below the tunnel level. Over a ton of this metal has been taken out up to Wednesday, and the whole of it placed in sacks. It shows plentifully of free gold, and while the whole of it is unquestionably rich, we cannot venture any opinion as to the value of the ore already extracted. This black metal is very deceptive in its surrender of precious metal. Some of it may be one-fourth gold, and again some similar in appearance may yield comparatively little gold. It is unquestionably true, however, that many thousands of dollars have been already taken out. The important truth demonstrated by this development is that the rich ore seams of this district run deep. Where the strike has been made is 600 feet from the surface, and over 400 from the upper tunnel level. There is no room for doubt that it is the same ore deposit which has been worked above; and the conclusion is irresistible that the vein runs the entire distance between the two tunnels, and also to unknown depths below the big tunnel. With this fact conclusively proven, Middle Bar mining district must rise in newness of life. The development of other promising claims will be pushed with renewed vigor. It is by far the most important discovery that has been made in quartz mining between Jackson and the Mokelumne river.

SOUTH SPRING HILL.—The last clean-up of this mill, made the first of the month, yielded over \$20,000, in free gold, without sulphurets. This is an average of over \$1000 per stamp; and reckoning one ton of ore crushed per stamp each day, makes an average of over \$16 per ton, exclusive of sulphurets. There is no other mine in the county, the Pacific alone excepted, that makes as flattering a showing. It is moreover, a comparatively virgin mine, just entering upon its career of gold production. Such is the estimate placed upon this splendid property by those who are in the best position to judge of its merits, that within the past two weeks the sum of one million dollars was offered for it, and refused by the owners. Negotiations are still in progress, with the probability that even this vast offer will be increased. At the mine a tunnel has been run from the side hill fronting the road, to tap the shaft at a depth of less than 100 feet from the surface. This is mainly intended as a precautionary measure, to provide an outlet from the shaft in case of accident to the works above. A new reel is being made at one of the foundries in Sutter Creek, for the new round wire cable, which is to replace the present flat wire rope. The mine and mill furnish employment to nearly 50 men.

MISCELLANEOUS.—At the Kennedy they are still making preparations to commence sinking. The shaft is being repaired where necessary. They are also changing one of the water buckets for a skip for hoisting rock. It is expected that in a few days more everything will be in readiness for sinking. The last dividend of the Plymouth Consolidated Mining Company was 75 cents per share. More men are being put to work at the Zeile. The force of miners is fast approaching to the number before the cave, and we hope shortly to report a full force at the mill also, with all the stamps in motion once more.

El Dorado.

A BUNCH OF COAL.—El Dorado *Republican*, April 26: About a year ago Hale & Baughman uncovered a bunch of coal in their hydraulic claim near Indian Diggings, which proved to be of considerable dimensions, though not sufficiently extensive to be called a bed. They have not yet reached the end of the bunch, though it is supposed that it is not much farther in the bank. The coal lies at a depth of 20 feet below the surface surrounded by gravel. The body is about 15 feet in height, 25 in width and is exposed for a length of 300 feet. In quality it resembles that found near Lone, being of a soft, loose texture, a brownish color, and burning with considerable smoke and flame. Last fall the deposit was set on fire and has been burning all winter.

NASHVILLE.—Nashville is virtually dead for the present. There are undoubtedly some good mines here and they will be worked at some time. All it needs is a little capital to start with. All the mining ground near this place is located and nearly all by parties who are too poor to do anything with it themselves. I am satisfied that if the Nashville mine were to fall into the hands of a mining man it could be made a paying property as soon as the water

could be taken out. There is some talk of the Central mine starting, but it is feared the report will amount to nothing. Dr. Smith, of Plymouth, says he is going to resume work on the old Sugar Loaf mine as soon as the weather permits. This mine used to employ quite a number of men, although it has not been worked for a good many years. It is situated about two and a half miles nearly west from here.

YIELDING WELL.—Placer *Observer*, April 24: Reports from the Slate Mountain mine are to the effect that the mine is yielding fabulous returns, and is by far the richest in the county. The Gopher-Boulder mine, near Kelsey, is being run at a 240 gait, and on ore, too, that promises well for the future of the mine. The El Dorado Water and Deep Gravel Mining Company are about to let a contract for running a prospecting tunnel into Texas Hill, a distance of 1,000 feet, at a point just below the old shaft.

Inyo.

WHITE HILL.—Inyo *Independent*, April 24: Two carloads of ore from the White Hill mine are ready for shipment. The mine is looking about as well as usual. Dan Hock is at work on his mine adjoining the White Hill; he is doing some dead work at present but will begin getting out ore in a few days.

Mariposa.

THE NORTH SIDE.—Coulterville *Cor. Mariposa Herald*, April 23: The whole country abounds in rich mineral veins of quartz, iron, cinnabar, copper and lead. We have good roads through all parts of the country. The present outlook for our mines is truly encouraging. The Red Cloud is showing up splendidly, producing some immensely rich ore. The vein is growing larger as they go down, and as it grows larger it grows richer. The company are putting in a new boiler preparatory to adding eleven more stamps to their mill or crushing capacity. Quartz Johnson has been here for several days with two English gentlemen making an examination of the Cook property. They left highly pleased with the prospect, and intimated that they would urge their company to purchase. If such should be the case, Coulterville will be all right again. Those mines, in the hands of a strong English company, would be worked for all time to come at a good profit to the owners. We are all hoping the sale will be made and the mines started up.

Mono.

BENTON.—Cor. Inyo *Register*, April 22: The concentration of low grade ores gains ground, and from what I can learn, with late improvements, the machines are proving a decided success. In thinking over the matter, I believe if a good concentrating works were established out in Indian or Clover districts, say at the old Banner mill, or better still, at Mrs. Morris' springs, it would be a paying proposition for a good company with capital enough to put up a good plant and pay their way. The mineral belt is very extensive and has never been thoroughly prospected, as the ores that were found were not of high enough grade to pay the excessive cost of transportation, though they cannot be said to be of very low grade. The few men who have devoted their time and means to the development of some of the ledges find themselves at the end of their tether and unable to do more; but enough has been done to claim the attention of milling companies and induce them to try their hand. A number of claims could be got hold of that carry not only low grade, but also high grade ores that cannot be profitably utilized under the present processes. Here are first the two claims of John King's and extensions that show every indication of being continuous and permanent ledges, giving assays from \$12 (the poorest looking rock) up to \$60, \$100 and \$200 per ton, principally gold, but with a percentage of silver. A test lot of 30 tons worked at the Montgomery mill, about a year ago, yielded enough free gold to show that it would pay, outside the cost of hauling; but in the tailings sluices there was found a grayish deposit that had to be shoveled out from time to time. Samples of this were tested by Dr. Griswold, and found to be a base of lead, with other metals, and gave assays of over \$200 in gold.

Nevada.

ON THE RIDGE.—Grass Valley *Union*, April 26: In the country below San Juan much interest is now manifested in quartz prospecting, owing to some recent discoveries, and one lead has been traced entirely across the country from the Middle to the South Yuba, passing a short distance below Sweetland, which is as much as 40 feet in width in places. It has prospected well in free gold at different points, and locations have been made over a long distance of country. If the good prospects continue, with the aid of water power, which can be made available, quartz mining may obtain a foothold in that section, where but slight attention has ever been paid to the business before. In the vicinity of French Corral a claim known as the "Slide" also shows quartz carrying free gold, that offers good encouragement for working. The prospects in quartz are sufficient to justify considerable exploration, and it is not improbable that good mines will be opened there.

LOCATED.—North San Juan *Times*, April 24: The quartz ledge recently discovered in the neighborhood of Buckeye Hill has been located for a distance exceeding 8000 feet by men residing at this place. It has been prospected the entire length, and gold in considerable quantities has been found all along the lode. Several old tunnels originally run by hydraulic mines strike the ledge at different places two and three hundred feet below the surface, and at each of these points free gold is found in the rock. At many places the owners are sinking on the ledge with a view of making a thorough prospect, and at 10 and 20 feet below the surface rich rock is found. One of the parties who is deeply interested in the ledge says it is the richest ever found in California.

DRIFTING.—Thomas Reese and Mr. Cunard have leased the Grizzly Ridge mine, near Columbia Hill, with the intention of working it by the drifting process. They commenced work on the mine last Monday. It is to be hoped they will meet with success.

PHOENIX.—Foothill *Tidings*, April 26: A clean-up from the Phoenix mine, 34 loads (nearly two tons a load), was milled, and yielded \$2,000, or \$58.82 to the load. The mine is looking well, but the water has been a great bother the past month or two. That will be remedied as the ground dries.

BANNER MOUNTAIN.—Grass Valley *Union*, Apr. 25: Considerable quartz mining prospecting is being

done in the immediate vicinity of Banner. There are a number of ledges thereabout. The North Banner Tunnel company has done much work out there in the way of mining development, and the property is held as valuable. The ledge in the main tunnel is showing strong and of excellent quality.

EMPIRE.—The twenty stamps of the Empire mill are kept running seven days of the week, and there are now 300 tons of ore on the mill dump, which shows that the underground work is pushed energetically. The North Star is also turning out a large amount of ore, supplying both the Larimer and Omaba mills of ten stamps each. There are 135 men at work in the North Star, including tributaries and those on regular pay. The ore is being taken out from seven levels from No. 4 to No. 13, the latter being the lower level.

Placer.

DUNCAN HILL.—Placer *Herald*, April 24: Mr. Geo. P. Johnson, joint owner with Mr. Goly in the Christmas-Gift quartz mine, located near Auburn, on Duncan Hill, showed us a specimen while in town last Saturday that he had recently taken out which weighed 10½ ounces, and which was nearly all gold. It was estimated to be worth in the neighborhood of \$150. He informed us also that the Oliver mine, on the same hill, known as the Southern Cross, is looking very well and turning out some first rate milling ore. Duncan Hill has been the scene of some rich finds, and yet, comparatively speaking, its surface has hardly yet been touched.

NEW MILL.—Placer Co., *Republican*, April 24: It is expected that the new stamp mill at the Lee mine will be ready for crushing next week. The owners have spent considerable money on the property and all their machinery, the engine, and track are of the best. They have made over 400 feet in the cross drift and have not reached across the channel yet. The Hoady mine adjoining is paying very well with only an arasta. The clean-up on the 5th inst., amounted to \$607, and on the 12th to \$460.

MORNING STAR.—Grass Valley *Union*, April 23: A test has been made of the rich gravel recently struck in the Morning Star drift mine, near Iowa Hill, and from a number of car-loads washed the yield was \$11.50 to each car. That beats the celebrated Bald Mountain claim at Forest City. The interests in the Morning Star are principally owned by the Messrs. Coleman, of Grass Valley.

FOREST HILL.—Cor. Placer *Herald*: Our town is prospering. Mining interests are in a thriving condition, with a certainty of an increased output from our bonanzas, when the "Excelsior," "Baker Divide," and other mines in this vicinity shall become fully developed.

STRIKE.—Placer *Argus*, April 22: A rich strike was made last week in a mine owned by Hamlin Bryan, Jose Romualdo and others, on Pine Flat Point, between Forest Hill and Bath in the Volcano Bar trail. The rock is said to be very rich, going as high as \$1000 to the ton.

San Bernardino.

CALICO DISTRICT.—Print, April 25: There is one branch of business in this district which indicates, in proportion to its extent, the amount of ore taken from the mines, and that is teaming. We were informed by Mr. McDuffee, of the Calico Freight Co., of Daggett, that they were hauling more ore now than at any time during the past. They have ten large teams constantly engaged hauling ore and borax and are two weeks behind in hauling owing to the unusual amount of ore on the various dumps of their customers. The large teams of Drew & Ball and Robt. McCue are also busily engaged hauling ore to the mills. There is more chloriding going on now than ever before, and the amount of ore taken out by chloriders is on the increase. The success of so many in this character of mining is an incentive to others to try their "luck," and where operations are carried on by miners who have had experience in handling the various kinds of ores in this district, their efforts rarely meet with failure. There are a number of undeveloped mines in the district, which, when thoroughly prospected, may prove profitable chloriding propositions, and eventually develop into good paying mines, as others have. Wm. S. Cranz has started leaching works for the reduction of ores near the foot of Main street. He has a tank that will contain 2½ tons. It is his intention before long to put in more tanks and operate on a larger scale. The leaching works of W. A. Sharp & Co., near the foot of Main street, are run to their fullest capacity, consisting of tanks that will hold thirteen tons.

RICH RETURNS.—The other day H. B. Stevens received the returns from a car-load of ore shipped to the reduction works at Kingman, Arizona, from his mine in Mineral Lake district, near Bagdad railroad station. Upon request he showed us the statements from the mill, which are as follows: Lot No. 1, consisted of 6894 pounds of ore, which gave \$1383.55 in silver, and 20 per cent copper. Lot No. 2, 9408 pounds gave \$711.52 in silver. Lot No. 3, 5195 pounds, 31 ounces in silver, 60 per cent lead, 45 per cent for each unit, total \$86.16. These returns speak for themselves, showing that the mine has substantial evidence of wealth beneath its surface. Such a high per cent of lead makes it a valuable mine for smelting. The above ore was taken out in 30 days by three men, amounting to about \$2200, realizing a handsome profit to Mr. Stevens. The 10-stamp quartz mill 30 miles south of Cadiz railroad station is now completed and will soon be in operation. The prospects of a thriving camp being established there are bright, and its output of bullion will no doubt greatly add to the annual output of San Bernardino county.

Shasta.

CHLORINATION.—Shasta Co., *Democrat*, April 22: De Forest, the assayer, is talking of putting up small chlorination works in connection with his assaying business. E. L. Reese is opening his mine near the county hospital with day and night shifts and having the ore crushed at Andy Fife's mill on Spring creek, with fair results. Our placer miners cannot complain this season of the lack of water. They probably never had a more propitious season for placer mining, as the rainy weather has extended almost into the lap of summer. The Blakemore Brothers of Deadwood made a handsome clean-up last week. They had been running two arastras, one fifteen days and the other a month, and realized from this run \$4500. Estimating that each arastra

crushed one ton each every twenty-four hours, the usual capacity, the ore crushed averaged about \$100 per ton. De Forest last week made a milling test of eight pounds of rock from the Carson & Snyder mine on Squaw creek. The sample was taken from the end of the lower tunnel, at a depth of 150 feet. The yield was at the rate of \$2080.75 a ton in gold. Another sample of five ounces, milling test, yielded at the rate of \$17,875 per ton. The above is a milling test for free gold. The sulphurets from the ore averaged 20 per cent and assays \$2085.60 in gold and \$35.70 in silver. There is a clay seam in the vein at this depth, about four inches in width, which samples from \$30,000 to \$50,000 a ton in free gold. How extensive this rich body of ore is the boys have not yet determined, but suffice it to say they see enough in sight to yield a handsome sum. The rest of the ore in sight, exposed by a 150-foot tunnel, samples by a fire assay \$33.77 a ton, and it is safe to say will mill with very little sorting \$25 a ton.

Sierra.

ALASKA.—North San Juan *Times*, April 24: We received a letter from Col. Bates, Superintendent of the Alaska mine, in which he says it is very annoying to him to have false rumors published of affairs at that mine. He says the mine is perfectly safe to the 400-foot level and work has been carried on almost uninterruptedly. The mill is running full time and as soon as the roads will permit a sinking pump, ordered hauled from the railroad to the mine, will be put in place, and we will quickly regain the 500-foot level. There is no stopping the progress of the Alaska mine. No extraordinary obstacles to be encountered can do it, and it is too well equipped to be endangered. All this is joyful news to us. What we said about the mine, to which the worthy superintendent objects, is that the mine had been flooded but was now worked on the 400-foot level.

ALASKA.—Mountain *Messenger*, April 24: The Alaska mine, at Pike City, has again got control of the flow of water in the mine and started the mill. The company will add 20 more stamps this spring, making 60 in all. The rock gets richer as they sink on the ledge. A piece about the size of a brick recently taken out contained \$1,000. The Pilgrim quartz mill, at American Hill, started crushing on Thursday last. The company has plenty of ore in sight, which prospects well, but how well it will mill cannot be told until a run is made. Work will soon be commenced to prospect for gravel in the old North Fork mine. It is reported that a new mill will be put up this summer on a quartz ledge at American Hill. The tunnel now being run for the extension of the Good Hope ledge is now in 200 feet, one-quarter the distance to which it is expected good paying quartz will be struck. Joe Parrena and Henry Limperich are running the tunnel.

THE COLOMBO MINE.—Sierra *Tribune*, April 24: The ledge in the Colombo mine is six feet wide, and two feet is very rich. The dump contains about 40 tons of ore. The principal work being done now is in a raise for air.

A GOOD CLAIM.—Saundershaus, Casserly, Bessler & Co. are obtaining some very flattering prospects in their quartz ledge, near Butcher ranch. A box of the ore was shipped the other day to Saundershaus, who is at present making his headquarters in San Francisco. The boys are exceedingly well pleased with the appearance of things at this stage of development, and are working with a will in order to get the mine in good shape this summer.

A PROMISING MINE.—At the Mercer claim, which is located 1500 feet east of the Florence mine, and is owned by the same parties, viz., Messrs. Mooney, Stephenson, Freeman and Hutchinson, the tunnel is now in 263 feet. The vein, which was cut through last week, is four and one-half feet in width and shows a very fine character of ore. At present an air shaft is being put through from the face of the tunnel to the surface, a distance of about 90 feet. When the shaft is completed the work of pushing ahead the tunnel on the vein will again be resumed, and operations in that quarter pushed ahead with all possible speed. From reliable information we have gained concerning this property it is quite certain to prove a paying institution to its owners, and one of the "solid" mines of Sierra City district. Twenty-seven ounces of ore taken from the Mercer ledge was assayed by A. Maltman after the foregoing was set up, and the result was a yield in gold of \$173.09 to the ton, and of silver, \$13.57 per ton. In the quartz assayed there was not any gold visible to the naked eye. This is a pretty favorable showing.

Trinity.

NEW RIVER.—Trinity *Journal*, April 24: There are from 80 to 100 men at the New River mines, and the quartz prospects of that district are very encouraging. It will be lively again this summer, and prove a permanent camp.

PAYING WELL.—We learn that a recent clean-up in the Enterprise mine at East Fork was very satisfactory to the new owners, McDonald Bros. and Levi Day. There were 26 tons of quartz crushed in the arastra and the yield was \$2,000. Some prospecting has been done and enough paying ore is said to be in sight to insure the early return of the purchase money. Mr. Barney McDonald is in charge of the Enterprise.

Tuolumne.

GROVELAND.—Cor. Tuolumne *Independent*, Apr. 24: The James Bros. are still running their arastra with splendid results. The mine continues to show rich ore and lots of it. Rumor says the ore pays from \$35 to \$40 per ton. Big Oak Flat is possessed of a five-stamp steam mill. The machinery is all on the ground, and we hope in a few weeks to hear the steam whistle. This mill is being built by Gosling & Co. to work the ore of the Mississippi mine, which they have bought. Mr. George Shirra is still running the arastra on the old dump of the Garner mine, and is very hopeful of the future of the property, and it is amongst the possibilities that there will be a mill there this summer. Reports from the Red Cloud mine are very encouraging. A rich strike is reported on the 350-foot level. The Kanaka mine has been doing well this season. The mill is shut down for a few days for repairs, but will soon start up and run as there is water in Indian creek.

GOOD OUTLOOK.—Union *Democrat*, April 24: While the past year has been one of depression, with dull business and necessarily great stringency in money matters, there is no reason for desponding.

This county is dependent more upon its mining resources than upon any other industry. The same rule applies to this as does to all other mining counties. They are subject to more vicissitudes than those sections that depend upon agricultural and manufacturing industries. Yet where there are good mines, the general average, for a series of years never fails in the end to make good returns, equal to the communities that depend upon the farmer or the manufacturer. For two years past mining has not had a fair show for want of sufficient water and unpropitious seasons. This year the heavy snows in the Sierra is a certain guarantee of a sufficiency, for extended operations late in the season. The breaking up of the storms are earlier and will give a longer season than for some years past. There is more than usual activity at this early date in mining operations that promises well for a good mining year. Already there are several mines where the developments are exceedingly satisfactory, and before the season closes are looked upon as certain to add to the wealth of the owners. Numbers of mining men are looking for properties to develop. There was never a brighter prospect for mining than is now presented.

NEVADA.

Washoe District.

HAILE AND NORCROSS.—*Enterprise*, April 24: The fine ore vein development above the 3100 level simply shows better and more extensive as further explored. It is over 20 feet or four sets of timbers in width, and of unknown length. Very little can be done to advantage just at present, however, in the way of wholesale ore extraction, owing to the lack of ample hoisting facilities, or until the Potosi drift is completed. On the 2900 level the main north lateral drift toward Savage is making good steady progress, and has passed to the northward of crosscut No. 4, with its face in low grade ore, with bunches of high grade. The connection being fully completed between this level and the 3000 by means of the upraise, a good air circulation is secured, giving excellent facilities for the extraction of ore from that point when required.

POTOSI.—The main south or northeast drift from the Chollar on the 3100 level was advanced 65 feet, making a total length of 420 feet from the Chollar line, or 540 feet from the switch in the west drift from the Combination shaft in Chollar ground. This Potosi drift has about 300 feet further to go in order to reach the south line and the Bullion ground. As it is being advanced at the rate of about 10 feet per day, it will probably take about six weeks longer. The ground through which the drift is passing is along the west side of the ledge, therefore nothing very interesting is expected until cross-cutting eastward into the vein shall be done. More or less quartz is met with, however, and being all virgin ground, 200 feet below all previous explorations, there is plenty of room for a first-class bonanza to be run into.

CON. CALIFORNIA AND VIRGINIA.—Daily yield about 400 tons, which is reduced at the Morgan and Eureka mills, giving assays from battery samples of about \$14 per ton. The drift being run to the southwest on the 1400 level for exploration purposes is in 685 feet. On the 1650 level the north-west drift has entered the old bonanza stopes, for which it was being run, in order to get at some good ore left at that point.

CHOLLAR.—Nothing doing in this mine at present beyond being an outlet for the waste run out through it to the Combination shaft on the 3100 level from the lateral drift south being run through the Potosi ground. No crosscutting or preparation to sink the Combination shaft deeper at present.

BEST AND BELCHER.—The water in the Osibiston shaft continues to be steadily reduced, and less than 100 feet has to be pumped out in order to reach the bottom of the shaft. Progress is necessarily slow by reason of the great extent of ground to be drained. The pumps are working excellently.

OTHIR.—Exploration work goes steadily ahead on the 300 and 400 levels at the north end of the mine, with no new features to relate beyond the starting up of a new crosscut west on the 400, which is in about 70 feet, showing merely vein porphyry and a little quartz.

MEXICAN.—On the 700 level the joint Mexican and Union lateral drift is now in 710 feet. Material in face, quartz, vein porphyry and clay, the formation being of a more favorable and encouraging character than heretofore.

ALTA.—The main north lateral drift on the 700 level is about 150 feet into the Benton ground, and has 100 feet further to go in order to connect with the old workings of the Lady Washington mine, toward which it is heading.

YELLOW JACKET.—The daily yield has been increased to 140 tons, the capacity of the Brunswick mill having been increased by additional concentration facilities. The old ore stopes above the 1300 level hold out and yield finely.

CROWN POINT AND BELCHER.—Daily output about 320 tons. The breasts and stopes of the 1500, 1600 and 1700 levels are said to be looking especially fine, and more ore comes from that point than heretofore.

GOULD AND CURRY.—The crosscut west on the 600 level continues in vein porphyry, with more quartz coming in. The southeast drift is advancing in quartz, porphyry and clay.

UNION CON.—The crosscut east from the lateral north drift on the 500 level is in 192 feet. Material, vein porphyry, with a little quartz and clay.

SIERRA NEVADA.—The west crosscut on the 500 level continues in an unfavorable formation of hard quartzite and dry vein porphyry.

KENTUCK.—Daily yield increased to 60 tons from the old upper workings above the 1300 level.

Belmont District.

NEW DISCOVERIES.—Belmont *Courier*, April 20: The Chicago Mining and Reduction Company's mine, under the able superintendence of D. H. Jackson, is fast developing into one of the largest and most valuable mines in the State. New discoveries of ore are constantly being made, and as this ore is of a high grade and a fine milling quality, increased bullion shipments are certain. The pump is working, and as soon as the incline shaft is drained, sinking will be resumed. When work was suspended in the incline a ledge was coming in that

carries ore of a good grade. Burleigh drills are on the way from San Francisco, and on their arrival will be used in the mine to expedite work. The mill is running steadily and giving satisfactory results.

EL DORADO NORTH.—County auditor and recorder W. F. Leon and John Griffin will work their mine—the old El Dorado North—this summer. In the early days of Belmont this was one of the most productive mines in the district, and why work was suspended and the mine abandoned has always been a puzzle to those acquainted with its history. Its present owners are well satisfied that they have a valuable mine that only requires the outlay of capital and the application of muscle, powder and steel to place it on a productive and paying basis. The resumption of work in the Belmont mines would gladden the hearts of the people of Nye's metropolis, but we suppose that resumption will be largely governed by the fate of silver.

Eureka District.

ORE SHIPMENTS.—Eureka *Sentinel*, April 24: Ore shipments from the mines in Eureka district to the two reduction works in town have been unusually numerous the past week. Ore shipments were made from the mines of the district to the two reduction works in town as follows: To the Eureka Con. works—Silver West mine, 1½ tons; Grant, 4; Silver Lick, 21; Phenix, 18; Alexandria, 2; Macon City, 4½; Seventy-six, 100; Dunderberg, 50; Morey, 1½; Iron Clad, 5. To the Richmond works—California mine, 95 tons; Eureka Star, 2; Iron Clad, 4; Tybo, 1½; Oriental, and Belmont, 6; Bullwhacker, 5; Rosalind, 4; Grant, 1; Adelphi, 6; Paul Wry, 2; Continental, 6½; Hamburg, 83.

TOO SOON.—The Richmond-Albion compromise is bringing back to Eureka a number of the former employees of the first named company, believing the settlement will enhance their chances for employment here. So far as known, the Richmond company do not contemplate any extensive operations in the near future—certainly not before July, if then.

Garfield District.

STRIKE.—Inyo *Independent*, April 20: There is report of a rich strike in Garfield district, near the Farrington Brothers' mine. Ore from the new find is said to go as high as \$1500 a ton. The claim belongs to parties in Dayton.

Hawthorne District.

THE NORTH STAR.—Walker *Lake Bulletin*, April 21: The appearance of the North Star is making the stockholders wear broad faces. Everybody will be glad to learn that the ledge on which they are now working, is twelve feet wide and gives fair assays clear across.

THE DICTATOR.—No doubt about the future of the Dictator, can now be entertained, as each day exhibits an increase in the size of the ledge.

Reveille District.

ORE.—Belmont *Courier*, April 20: The cholorides of Reveille are still taking out fine ore.

San Antonio District.

CHLORIDING.—Belmont *Courier*, April 20: It is expected that some chloriding will be done in the mines of San Antonio district as soon as the weather will permit.

Sprucemont District.

ORES.—Cor. *Elko Independent*, April 24: A company from Salt Lake City, in which Walker Bros. are interested, have made a contract with mine owners in Sprucemont for 100 tons of ore, to be shipped to that city. They have also contracted for transportation of the ores to Wells. The mines of Sprucemont are awakening up capital in the Utah country. They are found to be very remunerative, both to the miners and the mills.

Tuscarora District.

BELLE ISLE.—*Times-Review*, April 24: North drift from East crosscut, No. 1, 450-foot level, has been extended 19 feet. Belle Isle and Navajo joint crosscut, 150-foot level, has been extended 5 feet.

NAVAJO.—Crosscut No. 5, 350-foot level, has been extended 15 feet. South drift, east vein, 250-foot level, has been extended 13 feet. South drift, from Johnston crosscut has been extended 21 feet. East crosscut from west drift, same level has been extended six feet.

GRAND PRIZE.—North drift on the 200-foot level, extended 27 feet during the week. Stopes producing but little ore at present.

Tybo District.

LOOKING FOR A REVIVAL.—Belmont *Courier*, April 20: Tyboites are anxiously watching and waiting for a revival of mining in that once lively camp. Their faith is undiminished in the permanency of the mines, and they sigh and long for the day when capitalists will take hold of them and prove to the doubters and croakers that Tybo's mines are a permanent and profitable investment. Millions of dollars worth of bullion have been taken out of them and there is still a great quantity more waiting to be extracted.

ARIZONA.

THE LONGFELLOW.—Clifton *Clarion*, April 21: Is moving along as usual and extracting the regular quantity of ore. Development work is being pushed ahead, and occasionally large pockets of ore are encountered. Quite an amount of dead work has been done since the beginning of the year, and some considerable is yet in progress. The old standby continues to produce large quantities of excellent ore, and the mine is not nearly developed to the satisfaction of the management. No very deep workings have yet been reached, and judging from the mine's past record as an ore producer, millions of tons of high grade copper ore remains to be brought to the surface.

THE JOY MINE.—Is employing but six men at present, all that can be worked to advantage. The shaft is now 80 feet deep, and is being thoroughly overhauled, new ladder ways put in, etc., preparatory to extensive development. The prospect for a large body of ore is encouraging, as large quantities of black manganese ore are frequently encountered. The Yavapai and Modoc are being worked for all they are worth, and considerable bodies of good ore are being encountered. These claims though not quite so promising as many older claims, contribute their shares toward swelling the bullion output at the smelters. The Detroit as usual is turning out in quantity the rich ore for which it is famous. The usual number of hands are employed,

and no dead work is being done. The mine is in first-class shape, and the prospect for a bountiful output of copper ore for the second quarter of the year is encouraging. At Morenci the Detroit smelter is running smoothly, and turning out the usual quantity of bullion. The concentrators are housed, and are rapidly approaching completion. When finished, they will add materially to the product.

STATE OF MAINE.—Work still progressing on three lower levels, and usual amount of ore being taken out for shipment.

IDAHO.

PLACERS.—Idaho *World*, April 20: Heretofore placer miners on the other side of the basin have not been so soon in their mining movements as those on this side, but this season they were first to turn the water on. Claims around Placerville have been the scenes of operations for about three weeks.

HARDIN GULCH DIGGINGS.—Idaho *Messenger*, April 23: Johnny Rohrer gave us a few items of the placer ground discovered last fall by Rankin & Tibbits in Hardin Gulch. This gulch is situated on the west bank of the Yankee Fork—about three miles below Bonanza City in Custer County. The ground is, on an average, ten feet deep to bed rock. Mr. Rohrer says he was at the diggings a few days since and prospected the grounds—taking out as high as 50 cents on a shovel point. The gold is worth \$18 per ounce. He thinks Messrs. Rankin & Tibbits will be able to clean up 12 or 15 thousand dollars this year without much difficulty. We rely greatly on Mr. Rohrer's opinion as he is well experienced in placers, and a man of undoubtedly good judgment. Placers are too much neglected of late years. A little more placer and a little less quartz were better, gentlemen. Gulch mining costs but little, comparatively, and is an excellent forerunner to aid the development of our immense quartz interests. Let more men search for the God-milled gold.

MONTANA.

WICKES.—Cor. *Helena Independent*, April 22: The Helena Mining and Reduction company is Wickes, and Wickes is the Helena Mining and Reduction company. Without it there would be no camp and the grass would soon grow in the streets. The company employ about 375 men all told, including the miners at the Alta and the Comet, their monthly pay roll running from \$25,000 to \$30,000. In addition to this a large amount is paid out to woodhaulers in the vicinity. The Alta mine is distant from Wickes about two miles across the trail. The Alta mine has an almost inexhaustible fund of ore in sight, which is hauled over a good road two miles to Corbin, where the company's concentrator is situated. From Corbin to Wickes is but a short distance—possibly two miles. The Comet mine is about five miles from Wickes, on the other side of the gulch. A unique feature in this mine is the manner in which the ore is transported from the mine down the hill, a distance of over two miles, to the dump on the wagon road. A wire cable running over sheaves placed on poles about 100 feet apart, supports ore buckets clamped to, and suspended from the cable. The poles have arms similar to a telegraph pole, on the ends of which the sheaves are attached, so that the buckets swing clear of the poles. A small five-horse power engine is the motive power, and the smooth manner in which the tramway moves down the hill across a depression, up again, and over to the dumps, is a matter of surprise even to old engineers. The company have unlimited ore in sight at these two mines, and their bullion output is immense, working two shifts, night and day, including Sunday. While the ore is not particularly rich, carrying a heavy percent of lead with a trace of gold, it is very easily worked at a good profit.

BUTTE.—*Miner*, April 21: The week just closed has been one of steady and honest development work. Everywhere the report is the same—"the outlook never was better." No one is satisfied with the present, however, and everybody is sinking, drifting and exploiting. The output is constantly increasing, though not in an alarming manner, or in a way to indicate a boom. The increase is just what would be looked for in the natural order of events. Properties that were last year scarcely heard of, or appeared only as prospects, have taken their places alongside the producers, and their number is hopefully large and constantly increasing. Others are coming to that point and the number of producing mines will be largely swelled before the end of this year. The mills, concentrators and smelters are kept in operation to their fullest capacity. In all these institutions the order is improvement. The best methods applicable to our ores are employed. The experience of the best practice the world over contributes to the success of our mills and smelters. It is this vast output and the processes through which the output must pass previous to shipment to which we owe the fumes which occasionally settle down over the town, and which somewhat annoy strangers. The thicker the fumes the greater our financial vitality, and Butteites feel best when the fumes are thickest.

OREGON.

QUARTZ AND PLACER.—Jacksonville *Times*, April 24: Miners have again been made happy. The Jacksonville quartz mill is again at work. Considerable prospecting is still going on everywhere. The miners of Josephine county are busier than ever. The snow now lying on the high hills will keep up the water for some time yet. J. N. Castel has the Jacksonville Mining and Milling Co.'s tunnel in Timber Gulch nearly finished, and the prospects for plenty of good ore are favorable. Geo. Schumpf had several tons of quartz from his ledge in Willow Springs precinct tested at the Medford reduction works, and it milled from \$8 to \$12 a ton. John Miller who has extensive mining property on Farmer's Flat, finished cleaning-up a few days since, and is well satisfied with the past season's work. As he has much rich ground the yield of gold was considerable. A 16-ounce slug was recently picked up in Feldt & Co.'s claim on Althouse where so many big nuggets were found in former days. Wm. Felchly who is mining in the Red Dog district, Josephine county, is doing well having already cleaned-up several hundred dollars. The gold is mostly coarse, one piece weighing \$42.

The quartz mill at this place has been thoroughly overhauled, a larger engine procured to propel it, and crushing of ore from several ledges was resumed this week. We are quite certain that it will prove a success, if experienced mining men manage it. The heavy rains last week furnished the miners with a great amount of water, most of whom have as much as they had any time during the winter. Unfortunately a number of them were so far along with their work that they are unable to make the most of it. The others have resumed piking and ground-sluicing, however. Bybee & Hall have struck the pay channel in their mine on Canyon creek, and are taking out considerable dust. While in Grant's Pass, last week, Mr. Hall showed us about \$600 of as pretty gold as we ever saw, lying nothing but smooth, bright pieces, ranging from 50 cents up to \$25. This claim promises to be one of the best in that county.

GRANITE CREEK.—Bedrock *Democrat*: Prospectors are entering the Granite Creek country and making locations of quartz discoveries. Mr. Chas. S. Miller, of Monumental fame, arrived in our city last Sunday from the Granite Creek mining district and reports having re-located a valuable discovery of quartz on Greenhorn mountain, six miles west of Robinsonville. He intends returning to his claim in a few days and will put a couple of men to work at once developing. Mr. Miller is a mining man of experience and his judgment of mines is seldom wrong, and from the way the gentleman speaks of his discovery and the Granite country in general, we are led to believe that there is a great future in store for this portion of our country. A gentleman by the name of Boyd formerly of Wood River made several locations on this mountain, one of them an extension of the Miller claim, and is pushing the work of development as fast as possible. Mr. Boyd is the possessor of milling machinery in the Wood river country, and it is his intention at the present time to have the same shipped from there and placed on one of the ledges. Placer mining has started up this spring under very favorable circumstances and a large output of the precious metal is confidently expected.

UTAH.

REVIEW.—Salt Lake *Tribune*: The week has been stormy, with the inevitable bad roads, hindering ore shipments. The most notable event of the week has been the arrangement to start up the Mammoth mine at Tintic again. Mr. John F. Reese, an experienced handler of copper ores, to have charge of the treatment of the ore, for which purpose he will put up immediately a calciner. During the week ending the 21st instant, inclusive, there was received in this city \$23,999.37 in bullion and \$19,879 in ore, a total of \$143,878.37. The previous week there was received an aggregate of \$183,920.48 of which \$133,510.87 was bullion and \$50,409.61 was ore. The output of the Ontario for the week was 28,623.40 fine ounces; no ore sales. All is going on smoothly at the Ontario. The Daily produced during the week seven bars of bullion, 10,489.71 ounces, no ore sales. The base bullion receipts as reported day by day foot up for the week \$15,610; the fine bars \$31,771.00. The product of the Hanauer for the week was \$30,800. Of the Germania, four cars, \$10,647.83. Of the Pascoe, \$2030. The Stormont sent up \$350 in fine silver on the 19th. The Horn Silver remains locally quiet; no news from it. A small force is being worked but the output is insignificant.

STAR DISTRICT.—Cor. Salt Lake *Tribune*, April 24: The mining interests are all looking up. The whim on the Wild Bill mine has been completed. Shipments are now coming in from different mines and ores are being received from southeastern Nevada. The concentrating mill here is doing good work. The Monitor mine, South Camp, is showing up well, and most of the silver lead ores carry gold from \$10 to \$15 per ton, but should the tariff on lead be removed this gold could never be obtained. The Hickory, Adelia, Florence, Rebel, Jim Keene, Miner's Dream, Mammoth, Elephant, Burning Moscow, Creedmore and Talisman are shipping ores, and there is no end to the mineral wealth yet to be uncovered in this old and reliable district. The Cave mine in Bradshaw district is looking better, and shipments of ores from Beaver Lake district are being made.

THE CHRISTY.—Southern Utah *Times*, April 20: Everything is running smoothly at the mill and mines. Forty-five tons of company ore was crushed this week. The New Shaft continues to show up big.

THE STORMONT.—The outlook at the mines promise a fair month's run. Forty tons per day, of a better grade than has been mined for some time, was hauled to the mill last week. The stopes on five south, are prospecting well and furnishing a good grade of ore.

THE NEW LEACHING WORKS.—The soda which was delayed by the railroad strike in the east and bad roads between here and the Terminus, finally arrived last Tuesday and the leaching works were put in full blast again on Wednesday morning.

OTHER NOTES.—Taylor & Lampson shipped twenty-eight tons from the Leeds mine to the Christy mill, this week. Van Hagen, Goodman & Lawson, had twenty tons of Honest Miner ore crushed at the River mill this week.

AT THE MARSAC MILL.—Everything is moving on to the entire satisfaction of all concerned. About fifty men are employed there and all are doing good work. During the past week on an average of forty-five tons of ore per day was received from the Daly mine.

THE ROCK ISLAND mine looks well and Messrs. Volton, Sturridge & Co., are correspondingly happy. The stopes in the 200-foot level are producing a great deal of ore and about 200 tons of \$75 mineral is monthly shipped from the mine. Arrangements are being made to erect a new steam hoist in the mine.

THE MOULTON.—This is one of the best mines in the camp, and will remain so for years to come. Superintendent J. K. Clark reports everything in and around the mine to be in first-class condition. The ledges on the 700-foot level will soon be encountered, and the stopes in the 500, 400 and 300-foot levels are producing as usual. The splendid mill is in excellent condition and working regularly

TATUM & BOWEN,

25 to 31 MAIN ST., SAN FRANCISCO, and 91 and 93 FRONT ST., PORTLAND, OREGON.

We have recently furnished the Contractors the Machinery for

LA TRINIDAD
(300 Tons per Day)

—AND—

SILVER QUEEN
(100 Tons per Day).

These Mines are Located in Mexico and owned in London.

The Process is the Wet Concentration and the Plants are, without doubt, the most Substantial and Complete ever built.

We are Sole Agents for the Celebrated

ALBANY

Lubricating Compound,
Cylinder and Lubricating
OILS.

We make a Specialty of Lubricants for Export and Home Consumption.

...SOLE MANUFACTURERS OF...

**KENDALL'S PATENT
QUARTZ MILLS.**

Having renewed our contract on more advantageous terms with Mr. S. Kendall for the manufacture of his Patent Quartz Mill, we are now enabled to offer these mills at GREATLY REDUCED PRICES. Having made and sold these mills for the past five years, we know their merits, and know that they have given perfect satisfaction to purchasers, as numbers of commendatory testimonials prove. We feel confident, therefore, that at the prices we are now prepared to offer them, there is placed within the reach of all a light, cheap, and durable mill that will do all that is claimed for it and give entire satisfaction.

CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and
HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding homobastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 (XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

JOHN F. LOHSE, SEC'Y.

Office, No. 230 California Street

San Francisco, Cal.

THE CONSUMERS' COMPANY.

VULCAN B B AND AJAX.

The Best LOW GRADE EXPLOSIVES in the Market.

SUPERIOR TO BLACK OR JUDSON POWDER.

Vulcan Nos. 1, 2 and 3,

The Best NITRO-GLYCERINE POWDERS Manufactured.

SPECIAL INDUCEMENTS IN PRICES.

AJAX and VULCAN B B POWDERS are Unequaled for Bank Blasting and Railroad Work.

Caps and Fuse of all Grades at Bottom Rates.

VULCAN POWDER CO.,

218 California Street, San Francisco, Cal.

THE GIANT POWDER COMPANY

Manufacture Three Kinds of Powder, which are acknowledged by all the Great Chemists of the World as

The Safest and Strongest High Explosives in the Market.

GIANT POWDER or DYNAMITE,

Of Different Strengths as Required.

NORRIS'S EXPLOSIVE GELATINE, which contains 94 per cent of Nitro-Glycerine, and GELATINE-DYNAMITE, Stronger than Dynamite and even Safer in Handling.

JUDSON POWDER IMPROVED.

FOR RAILROADS AND LAND CLEARING. Is from three to four times stronger than ordinary Blasting Powder, and is used by all the Railroads and Gravel Claims, as it breaks more ground, pulverizes better and saves time and money. It is as dry as the ordinary Blasting Powder and runs as freely.

JOHN TAYLOR & CO.,

IMPORTERS AND DEALERS IN

ASSAYERS' MATERIALS, MINE AND MILL SUPPLIES,

CHEMICAL APPARATUS AND CHEMICALS, DRUG
GISTS' GLASSWARE AND SUNDRIES, ETC.

114-118 Pine Street, - San Francisco.

We would call the attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our full stock of Balances, Furnaces, Muffles, Crucibles, Scorifiers, etc., including, also, a full stock of Chemicals.

Having been engaged in furnishing these supplies since the first discovery of mines on the Pacific Coast, we feel confident from our experience we can well suit the demand for these goods, both as to quality and price. Our New Illustrated Catalogue, with prices, will be sent on application.

Our Gold and Silver Tables, showing the value per ounce Troy at different degrees of fineness, and valuable tables for computation of assays in grains and grammes, will be sent free upon application. Agents for the Patent Plumbago Crucible Co., London, England. Also for E. G. DENNISON'S Silver Plated Amalgam Plates. The plates of this well-known manufacturer are thoroughly reliable, and full weight of Silver guaranteed. Orders taken at his lowest prices.

Mining Engineers and Metallurgists.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific States.

From the official report of U. S. Patents in Dewey & Co.'s Patent Office Library, 252 Market St., S. F.

FOR WEEK ENDING APRIL 20, 1886.

340,122.—HORSE HAY RAKE—Byron Jackson, S. F.

340,333.—THRILL COUPLING—B. Liggett, Tucson, A. T.

340,381.—CUT-OFF FOR GAS BURNERS—Smiley & Stombs, S. F.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co., in the shortest time possible (by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Mining Share Market.

Mining stocks show no special improvement, nor will they unless something shows up on the Comstock of a very favorable nature. The present work on the lowest levels in Norcross and Chollar is watched with interest, for in case of a failure there it will stop further deep prospecting on the Comstock. The *Enterprise* says there is no present indication of such failure. On the contrary, the Hale & Norcross is looking substantially better and more promising than it has in the past year in its ore bonanza prospects, especially on or above the 3000. The main lateral drift south from Chollar, being carried through the Potosi ground, is showing very encouraging indications. This drift is running through a very interesting section. Nothing is known of the mine below the 2400 level; therefore, this drift is in a solid block of virgin ground, 700 feet deep, 700 feet long and of unknown width, showing room enough for a bigger bonanza than has yet been found in the Comstock at any point. Of course, all depends upon what may be developed in crosscutting east, as this drift is being run along the west side of the ore vein, and will be so continued through to the Bullion line, owing to the favorable formation the drift is being run in. No decisive movement toward sinking the Combination shaft deeper, or the resumption of deep explorations in Hale & Norcross, need be looked for or expected until this Potosi drift is completed, which will probably be in about six weeks.

Bullion Shipments.

We quote shipments since our last, and shall be pleased to receive further reports:

Moulton, April 19, \$17,600; Odessa Mill, 25, \$3,800; Barber's Mill, 25, \$2,500; Holberg & Co., 25, \$1,500; Alice, 17, \$45,483; Moulton, 17, \$18,656; Lexington, 17, \$50,496; Silver Bow, 17, \$10,060; Moulton, 23, \$20,208; Alice, 20, \$12,400; Hanauer, 20, \$10,810; Stormont, 20, \$3,250; Germania, 23, \$2,612; Alice, 23, \$16,055; Hanauer, 23, \$4,980; Queen of the Hills, 23, \$1,160; Kentuck, 24, \$16,000; Hanauer, 25, \$12,280; Pascoe, 25, \$1,750; Queen of the Hills, 25, \$1,150. For week ending April 25, Wells, Fargo & Co., of Salt Lake, shipped \$48,947 in bullion; McCormick & Co., \$47,920; T. R. Jones & Co., \$15,735; and Union National Bank, \$31,275. The Salt Lake output of base metals for the week ending April 24 was: Base bullion, 24 cars, 603,203 pounds; matte, 7 cars, 225,130 pounds; copper ore, 2 cars, 66,050 pounds. Total, 33 cars, 904,383 pounds.

New Incorporations.

The following companies have been incorporated and papers filed in the office of the Superior Court, Department 10, San Francisco:

UNION ELECTRIC CONDUIT CO., April 23.—Object, the construction of a system of underground conduits for the distribution of electricity. Capital stock, \$100,000. Directors—P. T. Dickinson, A. B. Hull, R. P. Clement, A. Everett Ball and J. M. Morehead.

TRUCKEE LUMBER CO., April 27.—Object, to conduct a general lumber business on this coast. Capital stock, \$50,000. Directors—E. J. Brickell, Spokane Falls; W. H. Kruger, Truckee; F. H. Horton, J. S. Maguire, San Francisco; W. A. Donaldson, Oakland.

GREY EAGLE MINING CO., April 27.—Location, Nevada. Capital stock, \$100,000. Directors—William Goldstein, Leopold Attenburg, J. J. Weglieu, Adolph Steinberger and Charles Attenburg.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

J. J. BARTLETT—Amador and Calaveras Co's.
E. W. INGALLS—Arizona.
E. L. RICHARDS—San Diego Co.
R. G. HOSFORD—Idaho and Montana.
Geo. McDowell—Santa Clara and Santa Cruz Co's.
J. B. PATCH, Nevada and Utah.
L. D. CLARK, Tehama and Shasta Co's.
M. S. PRIME—Alameda Co.
E. O'FLAHERTY—Butte Co.
M. D. SHARRER—Alameda Co.

A word to the wise: Use Muller's fine pebble water-calcies; 135 Montgomery St., n'r Bush.

Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, or beyond the time he intends to pay for it, let him not fail to write us direct to stop it. A postal card (costing one cent only) will suffice. We will not knowingly send the paper to anyone who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or some irresponsible party requested to stop it, we shall positively demand payment for the time it is sent. LOOK CAREFULLY AT THE LABEL ON YOUR PAPER.

MOUNT WHITNEY.—Captain J. M. Keeler, of Inyo county, delivered two lectures this week at Masonic hall, Oakland, on Mount Whitney, and the surrounding region. The lectures were illustrated by stereopticon views, many of them very rare and beautiful. Captain Keeler's descriptions were instructive and interesting. There is a freshness about his method of description which is not of the usual order in such lectures. He gave a great deal of information about a region very little known, even to citizens of this State—a region, too, not so very far from our centers of population. Capt. Keeler should be encouraged in his efforts to show up the wonders of our State, and his efforts are worthy of large audiences. Inyo county is a wonderful one in scenic resources, and there is a large fresh field there for tourist travel.

Complimentary Samples.

Persons receiving this paper marked are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber please show the paper to others.

THE LIDGWOOD MANUFACTURING CO., whose works are at Brooklyn, N. Y., have issued a very handsome illustrated catalogue descriptive of their improved hoisting engines, "L" horizontal engines, and stationary and marine hoilers. The engines, of which there are many forms, are all made on the duplicate part system. Hoisting engines of all kinds and sizes are illustrated and described in the catalogue.

Dewey & Co.'s Scientific Press Patent Agency.

UNCLE Sam has found it at last! A sure remedy for Torpid Liver, Sick Headache, Habitual Constipation, Chills and Fever, and all affections of the Kidneys and Liver. This is a New Compound, and one trial will convince you that it is the Cheapest and Best Remedy in the Market for Diseases of Kidneys, Liver and Stomach. If you want a pure vegetable compound, that is positively guaranteed to contain no mercury, go to your Druggist, and get a Bottle of the Arkansaw Liver and Kidney Remedy. Price, \$1.00 per Bottle.

(SCHILLINGER'S PATENT.)

—FOR—

**SIDEWALKS, GARDEN WALKS, CORRIDORS, OFFICES, CARRIAGE
DRIVES, STABLES and CELLAR FLOORS, KITCHENS, Etc.**

The Courts here and in the East have decided that Artificial Stone Pavements with plastic
concrete and in detached blocks, are infringements on the Schillinger Patent; and also, that
when the plastic material is hocked off with a trowel and cut through far enough to control the
cracking caused by shrinkage, that such pavement is in law the same as if laid in detached
blocks, and is an infringement of the patent. All property-owners having such pavements laid
without the license of the above Company, will be prosecuted.

HOOD'S FOUNDRY COKE.

Consumers are respectfully informed that owing to inferior brands of Coke having been sold in this and other countries under the name of "Patent Coke," the Glamorgan Coal Co. (Limited), Cardiff, in May, 1884, abandoned the title of "Patent Foundry Coke," substituting that of "Hood's Foundry Coke."

This Coke is exclusively used by the Selby Smelting and Lead Co., Union Iron Works, Professor Thomas Price, and other consumers here. Large quantities are regularly forwarded to Copper Smelters in Arizona and New Mexico, and also to consumers in Nevada and Salt Lake. The undersigned are the SOLE IMPORTERS of the above Coke, which is for sale in quantities to suit purchasers.

BRETT'S

Oxidizing and Chloridizing FURNACE.

A Continuous Furnace for Working the
Most Rebellious Ores.

For full description of this furnace see MINING AND
SCIENTIFIC PRESS of Jan. 30, 1886, or address the inventor
for circular.

The main features of the furnace are as follows: The
self-discharging dust-chamber and automatic return to
the cylinder when not sufficiently chloridized. A saving
of a large percentage of salt. Saving in weight of cylin-
der, which is short, as the greater part of the sulphur is
eliminated in the stack. There is less volatilization by
desulphurizing without salt. A higher percentage of
chlorination can be obtained by first desulphurizing, as
shown in the report of the Navajo mine at Tuscarora,
Nov. The separate fires give opportunity for perfect con-
trol of heat making it easy to roast the most rebellious
ores. By the constant motion of the pulp while being
desulphurized, there is no danger of matting. The com-
bination of flues and dust-chamber makes the construc-
tion comparatively cheap.

For further information, address

JENKINS PATENT VALVES.

Gate, Globe, Angle, Check and Safety.

Manufactured of BEST STEAM METAL. We claim the following advantages over other Valves and Gauge Cocks now in use:

1. A perfectly tight Valve under any and all pressures of steam, oils or gases.
2. Sand or grit of any kind will not injure the seat.
3. You do not have to take the valve off to repair them.
4. They can be repaired by any mechanic in a few minutes.
5. The elasticity of the Disc allows it to adapt itself to an imperfect surface.

In Valves having ground or metal seats, should sand or grit get upon the seat it is impossible to make them tight except by regrinding, which is expensive if done by hand, and if done by machine soon wears out the valve, and in most cases they have to be disconnected from the pipes, often costing more than a new valve. The JENKINS Disc used in these Valves is manufactured under our 1880 Patent, and will stand 200 lbs. steam. Sample orders solicited. To avoid imposition, see that Valves are stamped "Jenkins Bros." For sale by

\$1,000 CHALLENGE!

**THE FRUE ORE CONCENTRATOR,
OR VANNING MACHINE.**

**PRICE: FIVE HUNDRED AND SEVENTY-FIVE DOLLARS.
(\$575 00), F. O. B.**

OVER 1,000 ARE NOW IN USE. Saves from 40 to 100 per cent more than any other Concentrator. Concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order and ready to make tests at the Fulton Iron Works, No. 220 Fremont Street, San Francisco.

As the result of a suit East against an End-Shake Machine (the Embrey), similar to the Triumph, the Frue Vanning Machine Company owns the Embrey patent, and can put in the market an End-Shake Machine of earlier patent that will do as good work as the Triumph, and superior in construction and durability. There will be no risk of suit for infringement.

The Frue Vanning Machine Company warn the public that they claim and will prove the Triumph machine to be an infringement on patents owned by them.

Protected by patents May 4, 1869, Dec. 22 1874, Sept. 2, 1879, April 27, 1880, March 22, 1881, Feb. 20, 1883, Sept. 18, 1883. Patents applied for.

N. B.—We are and have been ready at any time to make a competitive trial against the Triumph, or any other Concentrator for stakes of \$1,000.

RANKIN, BRAYTON & CO.,
...BUILDERS OF...
MINING MACHINERY.

San Francisco: 127 First Street. Chicago: 100 N. Clinton. New York: 145 Broadway.

PLANTS FOR GOLD AND SILVER MILLS, embracing machinery of LATEST DESIGN and MOST IMPROVED construction. We offer our customers the BEST RESULTS OF 35 YEARS' EXPERIENCE in this SPECIAL LINE of work, and are PREPARED to furnish from SAN FRANCISCO or CHICAGO, the MOST APPROVED character of MINING AND REDUCTION MACHINERY, adapted to all grades of ores and SUPERIOR to that of any other make, at the LOWEST POSSIBLE PRICES.

We are also prepared to CONSTRUCT and DELIVER in COMPLETE RUNNING ORDER, in any locality, MILLS, CONCENTRATION WORKS, WATER JACKET SMELTING FURNACES, HOISTING WORKS, PUMPING MACHINERY, ETC., ETC., of any DESIRED CAPACITY.

WATER JACKET SMELTING FURNACES

For COPPER and ARGENTIFEROUS LEAD ores of NEW and ORIGINAL DESIGNS, covered by LETTERS PATENT. No other Furnace CAN COMPARE with these for DURABILITY, and in CAPACITY for uninterrupted work. MORE THAN 150 of them are now RUNNING in various parts of THIS COUNTRY, as well as many in FOREIGN COUNTRIES, giving results NEVER BEFORE ATTAINED as regards CONTINUOUS running, ECONOMY of fuel, AMOUNT and QUALITY of BULLION produced. These CLAIMS have been PROVEN BY RESULTS in ANY NUMBER of INSTANCES, and the GREAT SUPERIORITY of this SYSTEM of smelting ores DEMONSTRATED BEYOND QUESTION. COMPLETE PLANTS furnished to order of any CAPACITY, with ALL IMPROVEMENTS that experience has DEMONSTRATED as VALUABLE in this class of work.

Beyond question the cheapest and most effective machine of the kind now in use adapted to all grades and classes of ores.

This machine has been THOROUGHLY TESTED for the past TWO YEARS, under a GREAT VARIETY of CONDITIONS, giving most EXTRAORDINARY results FAR IN ADVANCE of anything EVER BEFORE REALIZED. A recent COMPETITIVE TEST at the Carlisle Mine in Mexico, showed an ADVANTAGE OF OVER 30 PER CENT in favor of THE DUNCAN. The amount SAVED OVER THE FRUE being sufficient to PAY THE ENTIRE COST of the machines EVERY MONTH OF THE YEAR. One of its MOST VALUABLE features is as an AMALGAMATOR. It saves all the AMALGAM GOLD and SILVER that ESCAPES the BATTERIES, PANS or SETTLERS, making the machine worth MORE than ITS COST for THIS PURPOSE ALONE.

Baker's Mining Horse Power.

Possessing all the requirements of a first-class hoist and affording means for the continuous operation of a Pump or Blower, without interfering with a hoisting apparatus. It is made entirely of iron, no piece weighs over 300 pounds. At the ordinary speed of a horse, a 1,000-pound bucket of ore may be raised 120 feet per minute. The hoisting-drum is under the complete control of the man of the shaft, and is capable of carrying 600 feet of five-eighths steel rope. SEND FOR CIRCULAR.

SEND FOR CIRCULAR.

SAN FRANCISCO GOLD, SILVER and NICKEL PLATING WORKS, 653 & 655 Mission St., San Francisco.

E. G. DENNISTON, Proprietor.

These Plates can also be procured of JOHN TAYLOR & CO., Dealers in Assayers' and Mining Material, 112 to 118 Pine St.

NOTICE.—Mining men are cautioned against purchasing inferior quality of Silver-Plated Mining Plates now being manufactured in this city. There has been a general complaint by purchasers that these plates proved defective in plating and short in weight of silver, assays showing great deficiency in silver guaranteed. Thin, light plating looks the same as heavy, but has no durability. Good plates can be furnished at same price these poor plates cost.

Working Low Beds of Gravel.

A few miles from Ione, Amador county, in this State, is the Arroyo Seco mine, which, as the Spanish name indicates, is in situated the bed of a "dry creek." The ground was known to be rich but all attempts to work it failed until J. P. Lambing took hold of the operation. The difficulty was there was no fall,

there were and ascertain prices, but resolved to have his made here. In addition to the engineer one man controls the movement of the bucket and derriok, and one man on the boom attends to the dumping.

The pay dirt is washed in sluices, as shown in the engraving. The tailings, small rocks, sand and water run into a general sump under the tall bonse shown in the accompanying en-

These 15-inch Knight Turbine wheels are giving great satisfaction. Mr. Lambing states that they were formerly running one No. 6 and one No. 8 vertical centrifugal pump with a 12-foot wheel of another pattern under 68 feet head, and 400 inches of water. They had to raise from 100 to 500 miner's inches 30 feet high, but the wheel required too much water, and the pumps so much oaro the present plant was substituted.

had from the East. This whole plant was made by Knight & Co., Sutter Creek, E. A. Rix & Co., agents, No. 20 Fremont street, this city. Miners who know of ground of a similar character to that described will do well to note the success achieved at Arroyo Seco.

TUOLUMNE MINES.—Another strike is reported from the Stanley mine, Tuolumne

MINING LOW GROUND WITHOUT FALL AT ARROYO SECO, CALIFORNIA.

and no way of getting rid of tailings. The pay dirt is about five or ten feet deep, and there is considerable stripping to do.

In order to get rid of the worthless top dirt, there is a large crane or steam derrick. The two engines to operate this are 9x16 inches, and there are two 48-inch upright boilers. They hoist from five to seven tons at a load, on the end of a boom 110 feet long. The dirt is hoisted 50 feet high, swung to one side and dumped, and the tub returned in one and a half minutes. The derrick-house containing the engines and boilers is on tracks laid on the ground so that it can be gradually moved up the creek as the claim is worked. With this derrick they can dump the "strippings" 110 feet on each side of the center, allowing the men to get at the pay gravel.

Mr. Lambing states that this hoist is much easier handled and controlled than those built by the Lakeport Derrick Co. builders who have the reputation of making the best, and it works in every way as well and in many respects better than those built in the Eastern States. Mr. Lambing went East to examine all

graving. Now these tailings and the water have to be removed as there is no fall and no way to get rid of them except to hoist them out of the way. This is accomplished in a very simple but ingenious manner.

In the sump are two submerged centrifugal pumps, of peculiar pattern, and designed for this particular work. Each has two 11-inch discharge pipes; the capacity is 600 miner's inches of water, or 900 cubic feet per minute. These pumps have no steps or bearings made under water, the whole weight resting on two 26-inch anti-friction wheels.

On the floor above these centrifugal wheels are two 15-inch Knight water wheels fed from the main supply pipe with 68 feet head. These wheels run the submerged centrifugal pumps below and raise the sand, gravel and water from the sump, throwing the whole debris and water into the flume seen issuing from the side of the pump-house. From this flume the gravel and rocks are shoveled out by men, the water is screened and again returned by a pipe, to be used in sluicing. Sixty-eight feet of water does the washing, pumping and all.

Mr. Lambing has been mining for the past 34 years and used all the wheels, but he now has five Knight wheels in use preferring them to others. This centrifugal double discharge pump will pump sand, gravel, chips, leaves, or anything that will pass through a three-inch mesh.

They have pumped up with the water sand and fine gravel as fast as two men could shovel it to the pump for hours at a time and raised it 36 feet high. These pumps have been in constant use for the past two years and it cannot be seen that they are any the worse for the hard usage, though the pumps brought out from the East wore out in five months doing the same work.

There is a large amount of mining ground throughout the Pacific Coast, similar to that at the Arroyo Seco claim, where the stripping is too deep to admit of working by the old process, but which can be perfectly worked by using these powerful steam derricks to remove the strippings. It is fortunate for the mining interests that these can be built here at the mines and at no greater cost than they can be

county. In a few days they are stated to have taken out \$7000 from the feeders running into the mother lode. The first big strike was made in 1882, when the owner took out \$11,000 in a few days. In 1885 the owner took out \$20,000 or more with arastra and hand mortar. This mine joins the Tuolumne and Willetta mines, which are reported as bonded to an English syndicate, for the round sum of \$150,000. A big ditch is being brought from the Tuolumne river, with the exclusive right of 3600 miner's inches. This ditch, as surveyed, will furnish plenty of water at the mill site for 500-horse power, by using Leffel's vertical mining wheel. The region thereabouts is active and promising.

NINE cargoes of coal came to this port from Puget Sound last month. Of these, five were from the Carbon Hill mine, two from the Black Diamond, one from the South Prairie and one from Seattle.

The quantity of coal now on the way to California is unusually large, especially from Australia.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eps.

South Fork Mining District, Shasta County.

EDITORS PRESS:—This district, named after the South Fork of Clear creek, lies in the foothills of the Coast range, about 20 miles west of Redding and 18 miles west-north-west from Anderson on the California and Oregon railroad, this being the stopping place for passengers and freight coming in from San Francisco. A good deal of placer mining was in times past carried on here and something is still being done in that line, mostly now by the hydraulic process. Quartz mining is at the present day, however, the principal branch of the business. There are two classes of ore here, the base and the free milling, the former, rich in silver, requiring to be treated by roasting or smelting, while the latter, which contains only gold, can be worked by the most cheap and simple methods, most of that heretofore handled having been reduced in arrastras.

The Gold Bearing Ore

Is found mostly in small seams of quartz running through the country and uniting with the larger veins at all angles. It is an ochreous ore, being composed chiefly of the oxide of iron. The gold is very pure and so entirely free that 95 per cent of it can be collected by simply crushing and washing in water. There are, perhaps, a dozen arrastras in the district running on this ore, which yields at the rate of about \$20 to the ton. These arrastras are driven by water and crush from one to one and a-half tons of ore per day. These seams being so narrow, usually from one to three inches thick, a great deal of barren rock has to be removed to get a little ore, rendering its extraction costly. Nevertheless, a good many miners have made fair wages working these small ochreous veins, the number of which is very great. They do not, however, penetrate to any great depth, rarely more than 40 or 50 feet below the surface. They are found sometimes traversing the upper portion of the larger veins as well as the country rock, and were obviously the sources of the placer deposits in this region. Though worked extensively for more than 20 years not a tenth perhaps of these small veins have yet been exhausted.

The Base Metal Lodes.

Nearly all the large lodes in this district except in the southerly portion, are silver bearing. The silver ore as a general thing is base, containing more or less iron and copper pyrites, sulphurets of zinc and antimony, galena, etc. The most of it is, however, of high grade, carrying from forty to sixty dollars per ton in silver and some gold. Considerable quantities of this ore have in times past been extracted and disposed of, some of it having been worked in mills here and some sold to the agents of various reduction works or shipped to markets abroad.

However disposed of, the returns have seldom proved satisfactory to the mine owners, who, on an average, have failed to get more than 30 per cent of what their ore was known to contain. Not only so, but adventurers coming into the district professing to be able to work the ore, have, after extensively sampling the mines, made a hasty departure, taking all the bullion they managed to extract with them. From all accounts the miners have fared badly at the hands of most parties with whom they have had dealings. Add to this the fact that the mills put up in the district have never succeeded in handling these ores successfully, and it is not at all strange that the business of mining remains here in a generally depressed and backward condition, notwithstanding the ore is mostly of high grade and developments show it to be present in great quantity in the mines. The lodes here have not been exploited to any great depth, the work being done by means of short tunnels, open cuts and shafts sunk in the vein matter. None of the tunnels cut the lodes at a depth of more than two or three hundred feet below the croppings, nor do any of the shafts reach a depth of more than eighty or ninety feet. Where intersected several of the veins show large bodies of ore, the most of them from two to three feet in thickness.

Geology and Vein System.

The country here consists of slate, granite, and porphyry, the granite occupying the middle of the belt, with the slate below to the east, the porphyry coming in higher up the mountain to the west. These formations run with the veins south 10 to 30 degrees west; the whole system pitching to the east, at a high angle, usually about 50 degrees. While the most of the lodes stand isolated in the country, others occur in broad ore channels, some of which carry several parallel veins. The contents of these channels aside from the ledge matter consists of decomposed quartz, all more or less metalliferous, clay, talc, porphyry, etc. That much of this material standing in these channels between the regular veins will pay for working, seems probable.

The More Important Mines.

Or those at least on which the greatest amount of work has been done in the vicinity

of the South Fork, commencing lowest down, are the following, viz.: the Black Diamond, occupying a fissure over a hundred feet wide, lying at the time of contact between the granite and the slate. The location covers two well defined parallel veins standing about 30 feet apart and showing regular clay lined walls. Three shafts have been sunk near the middle of the claim, one to a depth of forty and the other two to a depth of 80 feet each. They show the veins at these levels to be about four feet thick, three-fourths of the ledge matter consisting of ore that assays over \$100 per ton, and will probably yield by working process fifty to sixty dollars on an average. The hoisting and pumping here was done by water taken from the South Fork and delivered on an overshot wheel. The machinery is still in place though no work has been done on this mine for several years by reason of the refractory character of the ore, some of which was worked in a small cannon-hall mill standing near by. This mill so slimed the sulphurets that it was found impossible to save them with the Frue machine provided for the purpose. Other mills and concentrators are now about to be tried, but whether or not they will do any better work remains to be seen, though it is confidently believed that they will. This mill is also propelled by water taken from the South Fork, being a part of the water franchise that goes with the Black Diamond property.

This great contract fissure is taken up for a distance of three or four miles to the south, there being a great many valuable claims along it. Among the more promising of these are the South Extension of the Black Prince; the Crystal; the South Extension of the Crystal, the Arizona, the Confidence, and the Cincinnati, all of which make a fine exhibit of ore for the work done upon them.

Going up the creek one mile above the Black Diamond, we arrive at

The Chicago Mine and Mill,

Where more work has been done and a greater amount of improvements made than at any other point in the district. Here a ten-stamp water driven mill, furnished with concentrators, roasters, etc., was put up many years ago. Though a great deal of ore taken from the mine has first and last been worked here, the business has on the whole been a losing one, it having been impossible to save even one half of the silver the ore was known to contain. Both the mine and the mill have for several years past been idle, nor do the owners propose starting up either until some better plan has been found for working the ore. The ledge here which has been opened to a depth of 400 feet, carries all the way down a body of good ore fully four feet in thickness.

A little to the west of the Chicago another powerful vein was a few years since opened to a considerable depth and equipped with a first class mill. A short run on the base ore from the mine terminated the life of the enterprise, now in the same condition as its neighbor.

Journeying on up the South Fork,

We pass Strong's ranch, a beautiful place with vines, berries and fruit trees of every kind. Here also are mines belonging to the owner of the ranch, but, with the exception of the small free gold quartz seams, they are not now being worked. But like hundreds of others in the district they will be hereafter. A little further up we come to Ballou's place, where an arrastra is being run on the ochreous ores and some money being made. Ballou, to adopt one of the provincialisms here in use, wisely abstaining from "bucking at the base ore proposition," though owner of divers and sundry mines of this class. There is, in fact, hardly a resident of the district but can boast proprietary interests of this kind. Quarter of a mile further up at Meek's place another arrastra is being run here also on the same kind of mineral and with good results. Meek, lately deceased, was owner of a very valuable series of lodes, situated on the north side of the creek and a little higher up the mountain.

Another quarter of a mile further up brings us to the mill of the Chico Company now nearly completed.

The Mines of the Chico Company,

Lying on either side of the South Fork a short distance above. This is the live company of the district, being almost the only one that is just now spending much money here. The company is made up of active, energetic men, all miners of long experience and every one of them on the ground exerting himself to solve the problem that has here so long barred the way to success. That they will accomplish this end and that right speedily, I have not the least doubt. The mill, one of the Redstone patent, will be running in a few days. It is furnished with a Duncan concentrator and driven by water taken from the South Fork, the flow of which the company have a right of enough water to drive 50 stamps if required, the capacity of the present mill being about 15 stamps.

The company's mines in this part of the district consists of the Dayton and the Dayton North Extension; the Chico, the Chico North Extension and the Florence. The Dayton, the Chico and the Chico Extension, have been opened up to a depth of several hundred feet below the highest croppings on these veins, but little work having been done on the other claims. Large bodies of extremely rich ore have been developed here, assays of average

rock showing over a hundred dollars in silver to the ton, the selected running up into the thousands. Some of this ore is of the chloride variety and free milling. The bulk of it, however, is base, though the veins carry in places notable quantities of native and ruby silver. Where opened up, the ore bodies, at depths varying from 40 to 80 feet, are from 2½ to 3½ feet in thickness, compact and shapely. There are hundreds and perhaps it might justly be said thousands of tons of rich ore in sight here. A few rods further up the canyon are situated

The Mill and Mine of the Centennial Company,

Which, some six or seven years ago, made a large expenditure in opening their principal ledge and supplying it with what was then considered a suitable plant, the establishment consisting of a 5-stamp mill, rock breaker, roasting furnaces, etc. After roasting the ore here an attempt was made to extract the metal by the leaching process, which, having proved a failure, the works were shut down and have so remained since, but little ore having meantime been taken from the mines. The trouble here seems to have been the incompetence of the metallurgist in charge, lack of practical skill in this department of the business having in fact been the chief cause of disappointment throughout. The ores here are not specially base, nor are they otherwise much different from the class to which they belong found elsewhere, and which being successfully worked elsewhere, it is fair to presume they will sometime, and no doubt very soon, be successfully worked here. When that day arrives this district will become a great producer of bullion, as they have here not only the ore to make this possible, but all the natural facilities to insure cheap ore extraction and reduction.

Your editorial article in a late number of the Press on the subject of ore treatment by the new lixiviation process now practiced at the Lake Valley mines, New Mexico, has attracted notice and will be likely to greatly interest mine owners here, as promising a way out of the difficulties that have so long beset them. It is the many useful articles of this kind that appear in the Press that so recommends it to the mining public.

Natural Advantages.

The whole country here is covered with splendid forests of oak, cedar and pine, rendering the lumber and fuel supply cheap and certain. Water is abundant, several large streams flowing across the district, affording water for every needed purpose, the propulsion of machinery included. There is enough water here to drive 1,000 stamps in the summer, and an unlimited number at all other times. The deep canyons eroded in the sides of the mountains afford many eligible tunnel sites, while the decomposed granite favors the construction of roads and trails, many of which have already been built, leading to the principal mines in the district. The road leading from Anderson to the South Fork is so good that freight can be brought in from that place even in winter at less than \$10 per ton, the charge from San Francisco being only about \$15. The climate here is excellent and the soil so good that fruit of every kind can be grown to perfection and sold at lower prices than in the Sacramento valley. There being a great farming country close at hand, the staples of subsistence, the products of the dairy included, are cheap. Hay and grain can also be obtained in the mines at very moderate rates. Enjoying all these advantages, the business of mining in this country is bound to experience an early revival. The South Fork District is not dead, but sleeping.

PIONEER.

Xanthates.

Written for MINING AND SCIENTIFIC PRESS by C. H. AARON.

The xanthates, which I have taken the liberty of spelling with a Z in my books, otherwise xanthogenates, or, again, sulphocarbonates, offer a field for investigation which has been as yet but little explored, comparatively. I am not in a position to follow the subject up in a thoroughly scientific sense, but I have made some practical applications which perhaps deserve attention.

The volumetric assay of copper by means of potassium xanthate I have fully described heretofore in your columns, as well as in my book. The gravimetric assay, by the same reagent, has been merely touched upon. The former requires a certain amount of "skill and ability," also practice, and I find it is not a success in the hands of all. The latter may be easily executed by any one having a slight familiarity with chemical manipulation, and where copper assays are not of very frequent occurrence, is by far the more convenient.

The assay of copper by means of a xanthate is not so quickly made as that by the potassium cyanide process which is so much used at present and which is doubtless the best where assays are numerous enough to warrant the keeping in readiness of the apparatus and standard solution, where the ores are suitable and extreme accuracy is not required, but it is more rapid and less troublesome than electrolysis, which is, as I believe, equally accurate, or even, in certain circumstances, more so. In point of capacity of execution, it is about equal

to precipitation on iron or zinc, while far greater accuracy can be secured with less trouble and less skill.

Among the advantages of the method are:

First—A high molecular weight of the weighable product which contains only about one-third of its weight of copper. This admits of using a very small quantity of ore (or alloy) for the assay, one grain sufficing for the determination to less than one-tenth of one per cent, if a fine balance be at hand. The use of small quantities means economy in time and material.

Second—It is not necessary to remove nitric acid from the solution. (Difference from metallic precipitation.)

Third—Arsenic, zinc, manganese, nickel, earths or alkalis do not interfere. (Difference from the cyanide process.) Of all the substances which are liable to be present in the solution of the ore, as prepared, only cobalt, so far as I yet know, gives any trouble, and though cobalt sometimes exists in copper ores it is not of very frequent occurrence. Cobalt and nickel both interfere with the cyanide method. Tellurium would not be found in the solution; selenium I have not been able to try, but on general principles, and from analogy, I think it would be harmless.

Fourth—No special apparatus is required for the gravimetric modification, nor particular skill or experience, as with the volumetric and electrolytic methods.

In making this assay, I prefer to exclude lead and antimony from the first solution, though it may not be strictly necessary to do so; silver must be kept out. I therefore, as a general rule for ores, proceed as follows:

Digest 33 parts in any denomination of weight, or a simple multiple of that, as for example ninety-nine one hundredths of a grain, for which one grain may usually be taken as sufficiently accurate, of the powdered ore in a mixture of nitric, hydrochloric, and sulphuric acids in which the nitric is in considerable excess as compared with the hydrochloric, in a porcelain dish, with an inverted funnel as a cover to prevent loss by spurling, until the dense fumes of sulphuric acid come off. This takes but a few minutes in most cases. I use a small coal-oil stove for the work. If sulphuric fumes do not appear before dryness ensues, add more sulphuric acid; cool sufficiently and add a little water from a wash bottle, at first not removing the cover, afterwading rinsing that into the dish by the jet. Stir and warm for a few minutes, then decant on a coarse filter, receiving the liquid in a beaker. The solution is best not filtered very hot. Again add a little water to the residue in the dish; warm and filter. Complete the washing of the residue on the filter, receiving all the liquid, which need not be much, in the beaker. This first filtration may be omitted if the ore contains no silver, or not enough to make a material difference by its co-precipitation with the copper.

To the solution, filtered or not as above, add ammonia in some excess so as to dissolve all copper, and again filter, using a small, coarse filter for quick work, and wash with diluted ammonia as long as that passes with a bluetint.

To the ammoniacal solution of copper thus obtained add solution of potassium xanthate, while shaking or stirring, as long as that produces a (yellow) precipitate. Stir with a glass rod until the precipitate curdles and leaves the liquid clear on settling during a few seconds. It seems best to stir for a short time, then allow to stand for a minute or two, stir again, and so on till the liquid clears.

Filter through as small a filter as is convenient; wash three times with water at about 150 deg. F., and then, with a fine jet, wash the precipitate down from the sides to the point of the filter. Drain well and wash again with alcohol, dropping that on the edge of the filter, not disturbing the precipitate. At first, from dilution by the water in the precipitate, the alcohol will probably pass as a milky emulsion, then, as the water is displaced, it will clear. Continue until the drops from the filter no longer become turbid on dilution with water. (Test on a watch glass, etc.) Drain; dry on the water-bath or at heat of boiling water. Transfer from the filter to the weighing capsule.

If 33 parts of the ore were taken, the weight of precipitate in similar parts is the percentage of copper; or, the compound contains 33 per cent of its weight of copper. For practical work, if a grain of ore be used, one-third of the weight of the compound in hundredths of a grain is the percentage.

If the precipitate is well curdled before filtering, and well washed with alcohol at last, it will come off the filter cleanly enough for most cases, the small quantity remaining containing only about one-third of copper. If greater accuracy be desired, take two fine small filters, adjust them to equality of weight on a fine balance, place the one within the other and filter through both. After draining, remove the two filters from the funnel, separate them, unfold and lay them flat in a sheet of absorbent paper for a few minutes, then transfer them to the water bath for drying, and, in the weighing, place the empty one on the weight pan and weigh the precipitate on the other, filter and all.

In my next I propose to give some of the facts that I have been able to ascertain touching the reactions of the soluble xanthates on metallic solutions.

THE immigrant arrivals last week were about 8000, though but 5947 came to this city on emigrant trains, the remainder coming either first-class or stopping in other parts of the State.

To Miners Who Sharpen Their Own Drills.

Miners all over California are obliged by their situation to do their own sharpening, and while there are many who are good sharpeners and temperers, there are many more who are not. Probably very few understand the philosophy of working steel, and many will be glad to obtain some aid in the way of information as to how it should be done. The *Iron Trade Review* gives a few directions which are worth preserving. It says:

To work steel never heat above a light cherry red for hammering, then hammer light and quick until nearly black, as this improves the steel and will make tools that will do more than double the work than if not so treated. The hardness of steel is governed entirely by the heat when it is dipped in water; for instance, a piece of steel dipped at a bright cherry color and drawn in a straw will be very much harder than a piece heated to a dark cherry red and then dipped and drawn in a straw. Try it.

The forging, hardening and tempering of steel is an art that but few understand, as its knowledge is only gained by experience, and but few ever give its secrets to others; yet in a few words I will try to give the principal elements to workers of steel, which, if followed, will save you many losses, and give you a reputation for working steel that will insure you good and serviceable tools, as well as increase your gains.

Please remember that the heat at which steel is worked and hardened are two of the vital elements to produce good and serviceable tools. If heated above a light cherry red some of the vitality of the steel is destroyed, and it would in heating too many times return to iron. If heated too hot when hardening, it would fly to pieces, destroying your labor and steel, as well as give you a poor reputation.

Remember also to hammer your work lightly at a low heat, as this improves drills and edge tools most wonderfully, also take as few heats as possible, as overheating and too frequent heating reduces the steel to iron by destroying the carbon.

To harden drills, always dip them slowly to the depth desired in as near a vertical line as you can by the eye and hand, then move in a circular position until cold, but never any deeper in the water than first dipped, as this prevents them from cracking, which they would be likely to do if held perfectly still and the water formed a line around them. Do not change the water in which you temper, but as it wastes fill up the tank. If you are obliged to use fresh water always heat a piece of iron to put into it and bring it to such warmth as is perceptible to the hand, as steel is liable to crack when dipped in cold water. When you have heated your article to be tempered take it from the fire and examine to see if any flaws are observable in the steel, as this will prevent your having poor pieces of steel laid to your carelessness in hardening. In cutting up steel a thin, sharp chisel should be used, as a blunt one is liable to splinter or crack the bar, which will not be seen until it is tempered, when the labor is lost with the steel.

Alameda County Mining Interests.

Alameda county, which fronts on the bay where opposite San Francisco, has never been renowned for its mineral resources, but just now seem to be coming to the front. The *Livermore Herald* says: There is but little likelihood of an over-estimate, even in these days, when our attention is called thereto, of the mining possibilities of the Livermore mountains, when the operations are backed by brains and capital. We have been prospecting, by fits and starts, for 25 years, but with the exception of coal, there has been no discovery till within the last year, worthy of mention. The old prospectors sought for gold, silver, quicksilver and coal. They found traces of all these metals, but no quantity of any one. And had they struck a good mine, they lacked the capital and knowledge to develop it. Now, it is different. Practical men, backed by money, have taken hold of the matter, and at last these mining industries bid fair to be soon on a paying basis. Chrome already is, with our knowledge of the supply, increasing with every day. Our coal is excellent, and nearly ready for the market. The supply is almost without limit; and from present appearances our coal oil venture will prove a success. There is now every indication of striking a strong flow of oil within a week. If so, the company, which is amply able, will sink a dozen wells and pipe the oil to our town. We have other mines, which are in course of development, and bid fair to do well, and an intelligent prospect of our mountains is now in progress, during which it is most probable that other rich discoveries will be made. This all means business and growth for our town. We are just now beginning to realize the undeveloped resources of this section of country. The Indians saw here nothing valuable but the pine nuts and game; the Spanish cattle raiser appreciated the grass; the farmer came and found that he could grow wheat and barley and hay; another class saw our light lands and dry climate, and knew that here was the home of the vine; and now, men with practical knowledge of minerals are exam-

ining our hitherto worthless mountains and extracting wealth from the hoard of Mother Earth. Who will be the next to make a development of the resources of this favored spot?

The Sugar Pine of California.

In every practical sense and working quality it is equal to the white pine of the Eastern States—Susquehanna, Albany, etc., with the life herein noticed. It derives its name from the sugar-like substance that exudes to its surface upon exposure. It also contains considerable pitch and gum, which is the *is* referred to, inasmuch as their presence is somewhat detrimental, in that they cause shrinkage, and the pitch, unless held back by shellac or similar preparations, will force its way to the surface, through any number of coats of paint, and in special pieces containing an excessive quantity of the resinous matter, it is almost impossible to prevent blistering. This works bad when china glass finishes, or grained or polished work is instituted.

Fresh Water Seasoning

Is all that is required to make this product of the forests of California equal to any white pine produced in the United States. We have demonstrated this fact, and state it from personal experience. The more thorough and continuous, within reason, the water seasoning is to each separate piece, the more complete will be its effect in the removal of the superfluous, natural components of the wood. Raising and soaking in fresh water and transporting the rafts down rivers and streams to tide water, is about the best that can be done when the fresh water sources are available; but in California this auxiliary to seasoning is not possible. Our sugar pine grows inland, and is conveyed to market by teams or rail, or shipped on small vessels at certain points. Were it even possible to float it in the Sacramento or other fresh water rivers, there would be 30 miles of ocean salt water to cross, and the strong ebb and flow of the tide of San Francisco bay to encounter, before it could reach the market in this city. But even such rafting and floating, while it would improve the lumber to a considerable extent, would not wholly remedy the difficulty, for the reason that the large quantity of gum and sap in it can only be entirely removed by thorough soaking and friction. The bath process would nullify but not wholly dissipate the objectionable substance—still the benefit that any application of fresh water would be to sugar pine, would be worth all it would cost, where sugar pine is used for specially fine work or finishes. Reduced to its possible condition, the sugar pine of California would rank high among the white pines of the world.—*Cal. Architect.*

WESTERN COMSTOCK PROSPECTING.—Quite a number of prospectors have been scouting out along the western side of Mount Davidson during the past few days of pleasant weather, some making the lower portion of Washoe Valley their objective point of exploration. On this side of George Smith's ranch, parties have developed a fine ledge of gold and silver bearing ore, assaying from \$40 to \$60 per ton on the average. It is three or four feet wide, and shows very finely for a newly opened vein. A mile this side of there, other parties have found some good gold ore croppings. About half a mile to the west of Steamboat Springs, another party have commenced sinking a shaft under the potent direction of the divining rod, or indicator. They are very reticent, but say they know what they are about, and work with a lively will and good hope. If they do not strike brimstone and hot water soon, a drift east will fetch it sure.—*Virginia Enterprise.*

THAT NEW MINERAL.—All the newspaper talk about the discovery—about a year ago—of vast deposits of some unknown metal at Antelope will be remembered; how the State mineralogist finally decided that it contained nothing of value; how men were deceived by the product of iron in their crude attempts at analyzing, etc. Now transpires the practical part, which proves in the main that Professors Price and Soderling were correct when they said that the metal contained in the practically inexhaustible amount of gangue was sulphide of iron. Tests made in England show the stuff to be all important in the manufacture of fine steel blades, and a party willing to pay \$60,000 for the property is now getting out here after it. There are four owners besides Messrs. Benj. and Todkill, who may be congratulated even if their find did not prove to be tin or platinum.—*Bodie Press.*

STRAW GOODS are being manufactured on an extensive scale at a Mission street factory, where a large number of women and girls are at work making hats and bonnets. Pacific Coast dealers are relying on home manufacturers to a greater extent than ever before, and the prospects are bright for the building up of an exclusive trade, as there is a visible improvement in the quality of the goods made here, and they can be placed in the market at the same prices at which imported articles are offered. Some very fine work is being done at the factory referred to, especially that in which Milan straw is employed.

A Pioneer Ore Worker.

A *Tribune* reporter had the pleasure yesterday of meeting William Bruckner, the inventor of the revolving cylinder furnace bearing his name. He is here from Montana on mining business and will remain some time. His experience would fill a volume of interesting reading. Born in Germany, he was a student at Gottengen University and then graduated in the Freiberg Mining Academy. He first crossed this continent in 1864, when he passed through this city by the old overland stage. In 1866, just 20 years ago, he put in his first cylinder and took out the first metal brick at Black Hawk, Colorado. In 1869-70 he visited the Sweetwater, Wyoming mines, and reported there for Raymond's reports, published by the Government, and in 1870 he was given an escort from New Mexico to Mexico, to take testimony on some mines owned by American citizens. Discovering some rich silver-lead mines 100 miles south of El Paso, called San Domingue, he remained there till he sold out his one-third interest, and then going to Cincinnati engaged in manufacturing his cylinders. Wandering off to Germany, where he engaged in working copper, he remained abroad until 1879, when he came to Utah and put one of his furnaces in the old Flagstaff smelter. That is the only one in Utah, and it is now as good as ever, having been changed to West Jordan and placed in the works owned by the French company, now engaged in experimenting on a new reduction process. Within the past ten years Mr. Bruckner has traveled much, having visited various parts of America, Germany, Italy, Japan and Mexico. He is a member of the American Institute of Mining Engineers, which holds semi-annual meetings, the last one having been held in Pittsburgh in February. The next meeting, Mr. Bruckner informed the *Tribune* reporter, would be held in this city in August.

One object of the present visit of Mr. Bruckner here is for the purpose of putting in some furnaces for treating pyritous ores. He has lately taken out a patent for an improvement, combining the drying, desulphurizing and agglomerating processes all in one. This is done by having two revolving cylinders, one elevated enough above the other to permit ignition of sulphur while dropping from the upper to the lower cylinder.—*Salt Lake Tribune.*

THE Swansea marble quarry in Inyo county is opening up a large business. The quality of the marble is fully up to the highest standard yet drawn for it—that is, as good at least as the best known, no matter where found; there is no conceivable limit to the available quantity. The work now in hand, and likely to be for some weeks yet, is stripping to properly open the quarry before regularly beginning to extract merchantable blocks. Additional quarry men will be put on from day to day, or as fast as suitable men can be had, experienced marble quarry men being quite essential, for handling marble in place differs from any other rock and is a special trade in itself; for this reason suitable men are rather hard to find, though ordinary rock workers are plentiful. The C. & C. is now putting down a side track, which, in half a mile, reaches to the quarry. This will be largely used in getting rid of the vast amount of waste which cannot otherwise be easily disposed of, as the best marble lies below or near the surface of the valley adjacent. The company has not yet formally bound itself to furnish the 800 tons of marble for the Sharon gateway. The reason for this is, that in that quantity all to be of fixed sized blocks, all rather large, there are a number of perfect ashlers required, each of many tons weight. It seems there is not now a marble quarry opened in the world that could furnish such large and perfect blocks. While there does not appear to be a shadow of doubt about the ability of this quarry to turn out such, yet it is safer to wait until the quarry is properly opened before assuming the whole responsibility. Mr. Luce has already cut up good ashlers that were large enough—one that measured fifty tons. This marble quarry can but prove a very important industry for Inyo.

COMSTOCK UNDERGROUND FORESTS.—The *Virginia, Nev. Chronicle*, says: "No person unfamiliar with mining on a large scale can form an adequate idea of the amount of lumber daily consumed in timbering on the Comstock. The interior of the Con. Virginia hoisting works resembles a lumber yard in the morning before the timbers are sent below. At least 10,000 feet are piled around the shaft ready framed for lowering. The present daily consumption of lumber used in timbering in the various mines on the lode exceeds 100,000 feet, and requires the destruction annually of a small forest for that purpose to say nothing of the vast amount consumed for fuel in driving hoist and pumping engines. It is estimated that the trees required to furnish the lumber sent into the bowels of the earth to be used in timbering in the various mines on the Comstock lode would form an underground forest ten miles square."

MINERS on the Feather river in Butte county are talking about another tunnel through a mountain, by which to turn the river for mining purposes. This latter tunnel will be only 800 feet and will make 2300 feet of rich river bed to be in a minable condition.

FUNGI IN LUMBER.—A most important and interesting lecture was recently delivered before the New York Academy of Sciences in one of the halls of Columbia college, by Prof. P. H. Dudley. The subject, which was illustrated with the aid of the magic lantern, was "Fungi in Timber." The facts brought out as the result of long and thorough investigations made by Prof. Dudley, who has given this subject very great study, were exceedingly interesting and when given to the world must prove of great service in connection with the preservation and protection of timber and the relative merits of different woods for particular purposes, especially for railway use.

Prof. Dudley has been making investigations in this direction in connection with his work of examining the track of the New York Central, Boston & Albany and other railways with his dynamograph car and is entitled to the credit of having made several most important discoveries as to the qualities of various woods of this country, their liability to injury from different causes, the best means of protecting and preserving them, etc. So thorough have been his investigations and tests that there is probably no man in this country who would be better able than he to furnish the public such a book upon timber culture, protection, preservation, etc., as has long been needed. I do not know that he proposes undertaking such a task, but it is to be hoped he will do so. His address herewith referred to will be published in the forthcoming transactions of the Academy of Sciences, when I may have occasion to make more extended reference to it.

THE Ventura oil production is increasing. The *Democrat* says: "There has been no time since the oil wells were opened in this county that the petroleum interests looked so promising. The old wells are keeping up their lick, and newer developments are of a promising character. We are glad of this for a two-fold reason. The oil industry, as it increases, will add largely to the business and general prosperity of this community, and the pluck and energy of those who have stood to their guns through good and evil report deserve the heat of success. The steamers Santa Cruz and Al-x. Duncan have been supplied with iron tanks, in which they will carry oil hereafter in bulk, and as he most of this commodity on this lower coast is produced in this county, the increased facilities for shipping is a matter of local importance. The Santa Cruz on her last down trip discharged 85 tons of merchandise, and whilst unloading took on 25,000 gallons of oil, which is now conducted through a four-inch line pipe, from the tanks to the end of the wharf, thence to the steam-r's non-combustible receptacle. The Mission Transfer Co. expects to be able to supply the oil-carrying capacity of these boats every 10 days.

MOORE and Smith, of Stockton, have recently been shipping California lumber and shingles East by rail. The firm has before shipped shingles to Colorado and made the business profitable. Mr. Smith visited the principal cities of the East and sold large quantities of redwood and shingles. The firm has shipped over 90 cars of lumber to Eastern cities, including Boston and Albany, and to Chicago, Cincinnati, Detroit, St. Paul, Kansas City and other important points. A carload was recently shipped to Atchison. Mr. Smith says there is a great demand in the East for redwood which is found only in this State. It is used there for finishing and decorative work with fine effect, as Eastern mechanics have learned to polish it in the best style. One Eastern residence visited by Mr. Smith was finished inside with polished redwood and it was considered one of the most elegant houses in New York.

AGE OF FOREST TREES.—John T. Campbell reports some interesting observations upon the age of trees, which throw discredit upon the theory that wide, annual rings denote moist and fruitful years, and narrow rings indicate dry years. He finds that two neighboring trees, of the same description and the same age, will have rings of different characters in the same season. The healthiness of the tree, the amount of sun and moisture that it receives, the attacks of insects, the amount of suitable nourishment in the soil, etc., influence the amount of annual growth.—*Amer. Naturalist.*

THERE is a great and growing demand throughout the State for good lime and plaster. About 140,000 barrels are consumed annually in San Francisco, and the recent building boom will very materially increase the figure for the present year. Sonoma county is beginning to furnish some lime, as are also Marin and Napa. In the Santa Cruz mountains is found a very pure quality of limestone. It is of a crystallized formation and is easily burned. The outlook for the lime-making industry in all parts of the State was never better than at present.

A BIG LUMBER SUIT.—The Solicitor of the Treasury has instructed the United States District Attorney at San Francisco to bring suit against the Sierra Lumber Company to recover about \$221,800 damages for the conversion of timber and lumber taken from public lands. The special agents of the land office have been instructed to render the District Attorney all possible aid in prosecuting the suit.

TABLE OF CONTENTS.

EDITORIALS.—Working Low Beds of Gravel, 305. Passing Events; Sectional Names for California; Working Low Grade Rock and Sulphurets; Mining Accidents; Elevator Wells and Fires; California Iron, 308. Voltaic Batteries; A Cupel Machine; Burning Pyritous Quartz; An Old but Little Known Mining District; Contra Costa Coal, 309.

ILLUSTRATIONS.—Mining Low Ground Without Fall at Arroyo Seco, Cal., 305. Cupel Machine, 309.

CORRESPONDENCE.—South Fork Mining District, Shasta County; Xanthates, 306.

MECHANICAL PROGRESS.—Collapse of Boiler Flues; Science in the Workshop; Effects Produced by High Pressure; Inventions Wanted; Improved Mode of Decorating Metal Surfaces; Employ Only the Best Machinery and Tools; How to Use Files, 310.

SCIENTIFIC PROGRESS.—The Conservation of Energy; Echoes at Sea; Photography by a Lightning Flash; A Solar Cyclone; Forces Exerted by Great Storms; Restoring of Magnetism by Heat; Vital Power of Muscles after Death; The Air of the Sea, 310.

USEFUL INFORMATION.—Overworking Boilers; Leather-board; Bank Locks; Distemping; To Prevent Damp Walls; Water-Tight Brick; Paint for Wire Cloth; Zinc Test for Glue; New Galvanizing Process; To Keep Cistern Water Soft, 311.

GOOD HEALTH.—How to Live Long; For Diptheria; A Sanitary View of Burial; Cold Wet Weather; Borax as an Anti-Cholera Specific; How the Lungs Begin to Break Down, 311.

MISCELLANEOUS.—To Miners Who Sharpen Their Own Drills; Alameda County Mining Interests; The Sugar Pine of California; A Pioneer Ore Worker, 307. Notices of Recent Patents, 311.

MINING SUMMARY.—From the various counties of California, Nevada, Arizona, Montana, Idaho, Utah, Colorado, Oregon, Washington, New Mexico, 312-13.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Meetings, Assessments, Dividends, and Bullion Shipments, 316.

Passing Events.

The country east of the Rockies is in a state of excitement caused by labor strikes. Not only are the railroads affected, but lumber yards, furniture factories, flouring mills, coal mines, zinc works, agricultural implement factories, etc., are all in trouble. Lawless mobs in Chicago and Milwaukee have created riots in which several people have been killed, and the excitement still continues.

On this coast labor matters are quiet. The Governor has, at the request of the federated trades, made a legal holiday of Tuesday, May 11th, when there will be a procession or demonstration by the trades. But the whole matter is peaceable.

Mining matters develop nothing specially new outside of what we have noted in our Mining Summary. There continues to be a good demand for gold mines in this State, and just now there seems to be more intending purchasers than sellers, the buyers finding it difficult to get the class of properties they require—paying developed mines.

A POWDER JUDGMENT.—Judgment has been rendered by Judge Lawler in favor of plaintiff in the suit of the California Powder Works against the Blue Tent Consolidated Mining Company of California. The amount of the judgment was \$77,447.70 for material furnished, interest and costs. Some of the witnesses were summoned from Eogland.

Working Low-Grade Rock and Sulphurets.

In last week's PRESS we gave, in an article on "Mining and Milling in California," some facts concerning the Plumas-Eureka and Sierra Buttes mines, in this State, belonging to the Sierra Buttes Gold Mining Company of London. Since then we have received the report of the half-yearly meeting held in London, which develops some interesting facts, especially in the success of the chlorination works. In the Sierra Buttes the work for the past year showed an average value of ore of \$6.66 per ton, as against an average for the seven preceding half-years of \$6.91; the working cost was \$3.95 per ton, against \$4.33, the average of the seven preceding half years; and 25,250 tons crushed, against 20,628 tons. This shows that the cost of working has been reduced.

In the Plumas-Eureka the result of the half-year's work, though not so good as in previous times, is fairly satisfactory. The ore averaged \$7 per ton, as against \$7.32; the cost was \$4.89, against \$4.07, and tons stamped 28,194, against 28,347. It is noticeable in these figures that the small difference of 32 cents in the quality and 82 cents in the working made a difference of £6500. When a large quantity of ore is worked, a difference of \$1 or \$1.50 per ton very soon makes a difference of £6500, or nearly the amount of ore of the company's dividends.

In the case of the Plumas-Eureka mine the falling off in quality of the ore is that the flat vein which was a source of surprise and satisfaction at first has fallen off in quality, bringing down the general average. The additional cost was due partly to increased expense of working flat veins and partly to expense of a covered tramway which would admit of their working all winter. It cost \$15,000, but the mill was not idle in winter as would have been the case otherwise.

The chlorination works at the Sierra Buttes during the four months they have been at work have treated 136 tons, the average yield being \$188 per ton. This is from concentrates saved. This is nearly equal in fact, to the order of the whole ore of the famous St. John del Rey in Brazil—\$180. The working cost of chlorination at Sierra Buttes has been an average of \$24, thus giving a good profit on the sulphurets saved—\$164 per ton. During the six months they saved just the quantity treated during the four months, and they have a stock on hand that will let them go on for a time treating about 40 tons a month, but in the course of a few months they will naturally use up in that way the stock they have on hand and will then depend on their monthly savings.

They propose concentrating a little less closely than they have up to the present time so as to take in rather a larger quantity of pulp—some heavier grains of quartz—and they think they will, on the whole, get a larger amount of money, although the average yield per ton will be less. They do not expect hereafter to receive so large a return as during the first four months. That return has been over \$8000 a month (from the sulphurets) which has materially added to the monthly receipts.

The vein on the seventh level is of \$7 ore and shows no sign of diminution, and the discovery on the eighth level during the half year have been satisfactory, the prospects on the ninth being also good. The profits in the Sierra Buttes alone is about \$20,000 per month. These mines are making a good showing for low-grade gold ore in California.

Foundry Notes.

W. H. Birch & Co., of the California Machine Works, are building 750 sheaves and frames for the Hayes street cable road. They are also building four ten-foot sheaves and one eight-foot one for the terminal gearing. The switch gearing and other work is also being built by this firm.

There is very little mining machinery being made in this city at the present time. Business is very dull at the local foundries as has been the case for some time past.

The turn-tables for the Hayes Valley cable road are being made by the Phelps Manufacturing Co.

The San Francisco Tool Co. are at work on several pumping plants.

The lumber firm of A. M. Simpson & Bro. is now building at Coos Bay a steamer of about 70

feet in length to replace the steamer Novelty, recently sold by them to the Cutting Packing Company; also, another tug to assist in tows at Gray's Harbor. The engines will be made in this city. Captain Simpson also contemplates construction of a large ship for general freighting.

Sectional Names for California.

The propriety of subdividing California into several grand departments according to their geographical position, altitude, topography or other natural characteristics and giving to each such name as these peculiarities tend to suggest, or as may for other reasons seem appropriate, has somewhat occupied public attention and been from time to time discussed in the newspaper press. That a State covering such a vast area and so strongly marked in some of the particulars above mentioned might very properly be so subdivided and designated none will deny, the reasons for such course being numerous and obvious enough.

In considering this subject it has occurred to us that something like the following partitioning up of the State might be made to advantage; viz., let all that portion thereof lying north of Sonoma, Lake, Yolo, Sutter, Yuba and Nevada counties and west of the Sierra be called Northern California. Let the section extending from this department down to the northerly line of Monterey, San Benito and Fresno counties and lying west of the Sierra be designated Central California; all south of that line and west of the Sierra down to the northerly line of Kern county and following that line due east to the eastern boundary of the State to be called Southern California. For the country lying to the east of the Sierra Nevada mountains and south of El Dorado county we suggest the term *Trans-Sierra*, as being especially well fitted, many persons in writing about that region having already found it convenient to apply to it this name, which means over or beyond the Sierra. To justify the use of this prefix we have many precedents, as transcontinental, trans-val, trans-alpine, etc. Should many prefer it, the term *Eastern California* might be applied to this outlying portion of the State.

Some have already objected to naming any portion of the State Northern California, on the ground that the term is suggestive of a high latitude and a rigorous climate. There is, however, little weight in this objection. North Peru is hotter than South Peru, and the calling of one of the Carolinas *North* does not imply that it is materially colder than the other Carolina adjoining it on the south, much less that it possesses anything like an arctic climate. As well might be argued, that the term *Southern* applied to another part of California would be objectionable, as tending to convey the impression that the climate there is excessively hot as to suppose the term northern would prove misleading on this question of climate. We are of the opinion that the terms northern and southern, as already applied to these sections respectively, should be suffered to stand, being both appropriate and natural.

To the territory that covers the main Sierra north of Alpine county the term "Alta" or "Alpine" California, or some other word that conveys the idea of great altitude, might be applied. However subdivided, or whatever the names given to these subdivisions, the plan of partitioning up California in such manner as is here proposed, is a good one; and will, some day, be carried out. This State extends over very nearly ten degrees of latitude, and comprises within its boundaries vast areas of mountainous territory, great plains and valleys, with an immense extent of outlying desert lands—these several sections being both by location and natural features, broadly distinguished from each other. Out of these conditions there grows a necessity for recognizing this arrangement and assigning suitable names to these divisions which nature herself has already made, such as does not and never can exist in a country of limited extent and little diversified in its topography and climate. We have thus alluded to this matter not with the purpose of dictating exactly what should be done, but rather in the hope that having so broached the subject early and intelligent action will by our publicists and the newspaper press be taken upon it.

Elevator Wells and Fires.

The disastrous fire at the Bancroft building in this city last week, by which an immense amount of property was destroyed and several lives lost, has again called attention to the faulty construction of elevator shafts in high buildings. The fire referred to started in the basement, but by means of the several elevator wells leaped to the fifth story so rapidly that the employees barely had time to save their lives. The building was in a blaze both in basement and top story at once and in a few moments only after the starting of the fire. The wooden elevator shafts prevented the possibility of confining the fire to the basement.

The many suggestions made as to a means of providing iron trap doors in elevator wells at each story, which should open automatically to allow the elevator to pass and close after its passage, are not novel. Neither is it anything new to suggest brick shafts for elevator wells, which in case the fire entered, would simply lead the flame and smoke out the top without chance of setting fire to woodwork. But it would be new to do these things. The new Pioneer building has a brick shaft for its elevator, but scarcely another large building in the city has one. None, so far as we are informed, has horizontal iron doors to close behind the elevator.

The fault of the omissions cannot be charged against the architects, who recognize the danger of wooden walls, but against the owners who prefer the cheaper construction. The advantages of brick and iron are apparent and recognized, but the expense prevents their adoption.

It seems, however, if there is to be any improvement in this direction, it can be best brought about by the insurance companies. They now have a "compact" which lays down certain rules to which all companies agree. If the companies would all join in a firm determination to put prohibitive rates on wooden elevator shafts, and insist on a proper fire-proof construction of these important portions of a building, the evil would soon be done away with. They would be able, in fact, to enforce proper construction more effectually than any municipal resolutions. If owners found that their rates of premiums would be doubled or trebled on account of a cheap elevator shaft, they would soon see it to their advantage to build properly. It seems that none of the insurance companies held the Bancroft building in very high esteem, as it was a tall, wide shell, with no brick center or cross walls, and had four elevator wells. But still, insurance was effected upon it. If with each additional elevator well a good, stiff addition to the premium was called for on this and on other buildings, we should have much less danger to life and property from fire.

California Iron.

It is unpleasant to note that the smelting furnace of the California Iron and Steel Company at Hotaling, Placer county, has been closed down, and the men have been notified to vacate the dwelling houses. It is not believed that the works will be started up again for some years.

Iron mining and smelting has never been profitable on this coast. The Clipper Gap mine had no trouble in marketing its product, but when it came to compete in price with the imported article, there was no money in the enterprise. The disastrous fire a few years since was a bad set-back to the company, and the low price of iron since then has not given them an opportunity to reimburse themselves for the loss.

This was the only iron mine ever opened in California and worked to any extent. It was at first supposed that the enterprise would be a profitable one, and that the mines would prevent large importations. But such was not the case. English ships coming here for wheat cargoes could bring iron from abroad for exceedingly low freight, and they continue to do it. The Oregon iron mines have also been unprofitable, and one of them produced nothing last year. It seems strange that with all our mineral wealth on this coast, in the matter of coal and iron we are poorly off. And this is especially the case in California. The heavy expense of manufacturing iron here and the low price of the metal will prevent any further operations for some time to come.

Voltaic Batteries.

The wonderful progress made of late in new applications of electricity has created a demand for voltaic batteries that has taxed the energies of the manufacturers to supply. The telephone business of this country alone requires over one million cells, and the extension of telegraph systems, railroad signaling, district fire alarms, messenger service, bell-ringing, etc., has added another million within the past three years. It is estimated that over 5000-horse power of energy is being supplied by batteries in this country alone. The consumption of zinc is therefore very great, and as this is the only metal generally employed, the price has remained very firm and is likely to continue for some time to come. This fact should be carefully considered by the owners of zinc mines, as their value is likely to become much greater. We say this in view of the fact that the question of electric lighting from voltaic batteries has been solved, and several companies have been formed in the East and in Europe to develop and introduce different systems. The field that these companies propose to occupy is a very large one, and unless some other metal is found to replace the zinc that is now furnishing the fuel in nearly all voltaic cells, the consumption will be simply enormous.

A careful review of the patents that have been granted for voltaic batteries leads one to the conclusion that many inventors have been working upon the "cut and try" principle; and a study of their specifications shows such a diversity of language and want of scientific and technical knowledge, that the examiner becomes confused and reaches the conclusion that said inventors do not fully comprehend the subjects they are discussing. This is not to be wondered at, perhaps, for it is a lamentable fact that science has not yet fully settled what the chemical combinations and reactions are that take place even in those voltaic cells that have been longest in general use.

This is perhaps the reason why so little progress has been made in hydro electric batteries. That they are still open to great improvement is fully demonstrated by results lately obtained by the use of chromic acid in contact with the carbon electrode in a "zinc-carbon" cell. If this acid should be employed in the future to any great extent for battery purposes there will be found a good market for the chrome iron that is known to exist in quantity upon this coast, the price for which at this time little more than covers the cost of mining and is commercially controlled by a few individuals.

We are, however, as much in the dark as ever regarding the chemical reactions that take place in the so-called "chromic acid battery," and we urge upon our chemical educators and students the necessity of solving the many problems that are presented in the different kinds of batteries now in the market, and to join hands with the electricians in developing a battery that will be scientifically correct, cheap and effective. The cause of the variations in the electromotive force of batteries should be explained, and, if possible, overcome.

The cause of the internal resistance of batteries should be made known, for the economic problem of electric lighting from batteries depends upon reducing this internal resistance to a very small fraction of the total resistance of the circuit. A fortune awaits the inventor who can use a cheaper metal than zinc, even though a greater number of cells be employed to produce a given result. A careful study of what is known as "secondary batteries" may lead the inventor to devise a primary battery, the economy and efficiency of which may prove to be superior to any yet known or employed. The sulphates of the higher oxides of certain metals when used as electrolytes in contact with the metals from which the oxides are derived produce a battery that is generally employed for long, heavy and continuous work—as is fully illustrated in the different forms of what are known as gravity batteries, of which the Daniell cell is the first and standard type.

That copper and zinc are the only metals that have been generally employed in this class of cells seems to be a strange condition of things, and from what we have lately seen, by the combination of other metals with the sulphates of their higher oxides, and for which patents are now pending, we conclude that the days of zinc and copper are numbered and that iron and carbon will eventually take their

place. Aside from the sulphates of the metals employed for battery purposes, are the nitrates and chlorides, also largely employed for special purposes; and we believe that the best combinations for the transformation of chemical action into electricity is yet to be discovered. Perhaps in Nature's wonderful laboratory may yet be found the happy combination that will solve the problem, as petroleum has that of illuminating oils.

A Cupel Machine.

At the School of Mines, Rolla, Missouri, they have a machine for making cupels uniform in size and density, which has proved quite satisfactory after four years use. Professor Chas. E. Wait described the machine to the American Institute of Mining Engineers, and presented an engraving which we here reproduce.

As shown in the accompanying figure, it consists of a common letter-press, the movable platen of which has been removed. In place of the plate, there is attached to the screw a plunger, which turns with the screw, moving up and down, and making the depression in the cupel. The ring holding the bone-ash is held in place directly underneath the plunger by a wooden guide fastened to the base of the press. There is also fastened to the top of the guide for the ring, at a distance above the base of the press equal to the height of the cupel-ring, a

CUPEL MACHINE.

piece of wood about 3 inch thick, under which the ring will just slide into place, and through which there is cut a circular hole exactly fitting the plunger, guiding it in its downward movement always in the same vertical line; this last guide not only directs the plunger, but also prevents the lifting of the ring by the plunger, upon the raising of the latter.

There is also a small spring (not shown in the figure) which is arranged to push forward the ring after the ash has been compressed. As soon as the plunger is raised and the finger removed from the ring, it is pushed forward by this spring several inches, clearing both guides to a position on the front of the base of the press, from which it is taken to a simple contrivance for removing the cupel.

To make a cupel, fill the ring with slightly moistened ash, the plunger being raised just high enough to allow the ring to be put in place with the left hand, holding it with the left thumb. With the right hand give the wheel to which the screw is attached about one turn, depending upon the pressure required; reverse the wheel until the plunger is raised, and remove the thumb suddenly, at which moment the spring will push the ring to the front.

Cupels of any size may be made by having plunger, ring and guides to suit. I have been making three sizes: 1½ inch, weighing 18 grams; 1¼ inch, weighing 37 grams, and 1½ inch, increased depth, weighing 48 grams.

THE Arizona Citizen of April 30th says: The Quijota properties, known as the bonanza mines, were to-day attached by the Nevada Bank of San Francisco, for money loaned, amounting to less than \$30,000.

THE receipts of coal at this port in April were 54,000 tons, making total receipts since June 1st of 223,000 tons, against 306,000 during the same time last year.

Burning Pyritous Quartz.

In Victoria and New South Wales many of the miners believed in burning their sulphuretted ores before amalgamation and others thought it a detriment. The Government officials made a pretty exhaustive examination of the subject and obtained the opinions of many superintendents who had been experimenting. As a result of these investigations, the Mines Department reported that they considered it very disadvantageous to burn the pyritous quartz previous to crushing. A summary of their conclusions will interest California miners who have ores containing small percentages of sulphurets.

In the first place, supposing the ore only to contain true pyrites (species free from galena), the burning, however, carefully conducted, would not effect a thorough roasting of the pyrites, but produce, as it were—and as can be observed on examination of kiln-burnt mineral—three different stages. One part of it, in the center of the larger quartz fragments, is generally but little affected; another part is converted into a lower or mono-sulphide, which, in contact with clayey and silicious dust, produces hard, glassy slag coatings on the outside of the ore. The third part, that on the surface of fragments, freely exposed to the access of air during burning, is well roasted, i. e., converted into powdery sesqui-oxide of iron,

with its originally contained gold disseminated through it in microscopical particles.

Now, on subsequent crushing and amalgamation of the burnt mineral, the gold of the slightly affected pyrites cannot, or but very imperfectly be extracted by the common amalgamating appliances, whilst that distributed through the mono-sulphide of iron, the hard slag coatings and the iron sesqui-oxide is, to a great extent, lost; that of the first body through being too much enveloped, and the mono-sulphide itself being besides liable to sicken the mercury; that of the hard slag coating through being glazed over and is generally, with very great difficulty, liberated; and finally, that of the well-roasted mass, on account of its finely-divided state, which renders it liable to be carried off by the stream of water without ever coming in contact with the mercury.

Should the ore contain galena, or association with the pyrites, not only would the loss of gold be considerably increased, but quicksilver would be lost in notable quantities, the cause of this being the partial reduction or conversion of the galena, in contact with the burning fuel, into lead, a metal which, as is well known, sickens the mercury. If this amounted to less than one per cent, rendering concentration not profitable, the burning of the quartz previous to crushing would, like that of ore containing no pyrites at all, be advantageous, on account of the lower reduction of the burnt ore. It must, however, be remarked, that with any ferruginous quartz, there could also be a likelihood of the formation of the above-noted hard slag coatings over the surface of the fragments, with a consequent liability to loss of enveloped fine gold particles during crushing.

TWENTY young girls from the Scotch manufacturing towns arrived in East Oakland on Monday, to work in the cotton mill at that place.

An Old but Little Known District.

We publish elsewhere in this issue of the PRESS a letter from a valued correspondent, descriptive of the South Fork mining district, Shasta county. What is noticeable in this communication is the fact that this letter brings into view a mining locality of which the general public has heretofore had little knowledge. It is, indeed, highly probable that not more than a few of our readers ever before heard of this South Fork district, or even supposed that there existed such extensive deposits of the precious metals so far south in the Coast Range, a region generally regarded as exclusively a grazing country. And yet, this has been an active mining locality for more than thirty years. In the first place this was the site of placer operations, which, commencing early in the fifties, were continued for fifteen or twenty years, hydraulic washing being still carried on in this district. In the winter season when water is plenty some ground sluicing and gulch washing are also practiced.

Some ten or twelve years ago vein mining was here engaged in, a dozen or more arastras having since been kept steadily running on the free gold ores found in the small ferruginous quartz veins, of which there are many in the district. But little headway appears, however, to have been made in this department of mining, owing to the refractory character of the great mass of the ores, which are largely silver-bearing. As these ores are of good grade this district ought to present an inviting field for parties having the means to successfully handle them, in which light it is worthy the attention of the "process man." Here would also be a good place for experimenting with concentrators, roasting furnaces and the like, particularly those supposed to possess any special fitness for treating base ores. Wood and water are represented to be plentiful in the district, which can be easily and cheaply reached from San Francisco. Few mining localities seem, in fact, to be better situated as regards natural advantages and accessibility than this. The location of this South Fork region, so far south in the Coast range and close on the borders of the "cow counties," tends to show how the mineral, the grazing and the grain-growing districts of California run into and almost intermix with each other, the fruit-raising territory covering them all.

Contra Costa Coal.

The only coal mines in this State that have been at all productive are those known as the Mount Diablo, in Contra Costa county. The coal of late years has not been so much used for domestic purposes as formerly, better qualities coming from abroad and from the Puget Sound region. Moreover, the Mount Diablo mines have been gradually reducing their product, and within a year or two some of them were shut down, and the little mining towns and settlements thereabouts have in consequence lost much of their population. As a steam coal that from Mount Diablo has always been popular and is largely used. The mines were well equipped and properly opened, but from various causes some of them did not pay. Now, however, it looks as if there would be a new lease of life for the coal mining region of Mount Diablo. In 1884 James Rankin and George Hawxhurst leased the Pittsburgh coal mine for a term of five years, and began running it under the name of the Somerville Coal Mining Company. The great depth of the mine made it very expensive to work, and as the cost of the mining was about equal to what the coal could be sold for, they soon realized that something must be done to reduce expenses. Consequently, they ran a tunnel some 700 feet in length, at a cost of about \$2500, and on Friday of last week a vein of coal about three feet in width was cut, and they are now taking out 50 tons of coal per day, with the prospect of an increase to 100 tons. A ready market is found for all that is taken out, and the discovery has brought new life to that section of the county. Men are flocking that way, with the hope of steady employment, and instead of the mines having to be shut down, the houses sold for just what they would bring and the town abandoned, as was the case at Nortonville, there is every prospect of Somerville increasing in population and assuming an air of prosperity.

MECHANICAL PROGRESS.

Collapse of Boiler Flues.

In view of the importance of the object, we cannot do better than point out the respective causes of danger.

First, with regard simply to the danger of collapse in the flues of large diameter; it is well known to engineers that the resistance of wrought iron to the compressive strain to which a flue is subjected, is much less than its power of resistance to the tensional strain to which the shell is subjected. Here is the first inherent weakness in flues with material of the same thickness as in the shells. Diameter is a great factor in either weakness or strength; that is to say, the larger the flue the greater is its tendency to collapse, and on the average the diameter of flues in marine boilers is on the increase.

Similarly, the greater the length of the flue unsupported, the greater its liability to collapse; this can be avoided by the introduction of flanges or supporting rings at different points in the length of the flue. Theoretically, a flue is, when perfectly cylindrical, in its best form to resist collapsing pressure, as the pressure is all then resolved as compression upon the material. Should, however, any deformation in the shape of the flue occur from this perfect cylinder, the tendency to collapse is very much increased in the direction of the flattened sides.

Now, in all cases where flues do eventually collapse, it is probable that they show a previous deformation in the direction in which they are about to collapse, and the proper notice of this change of form would frequently suffice to warn the engineer in charge, who might, by staying, prevent ultimate collapse; or, at any rate, reduce the working pressures until the danger was removed. The examination of flues, as to their maintenance of form, should be regularly conducted from time to time by means of a suitable gage-bar, which could be easily inserted at the end of a rod and tried in different directions to ascertain whether any deformation was setting in. This, in practice, is seldom done, as engineers in charge of boilers are apt to overlook the immense increase of danger of collapse after a very slight deformation has commenced.

In raising the question as to whether collapse may not be due, in the first place, to heavy incrustations on the heated surface, we would say that such incrustation, tending to allow the temperature of the plates to be raised, very materially reduces their strength, and thus hastens change of form and ultimate collapse. It is quite possible that an engineer, in his anxiety to avoid corrosion, knowingly permits incrustation to a certain amount to accumulate upon the inside faces of his boiler plates, and there is no doubt that a thin layer of such incrustation is a great protection against corrosion, but it is easy to overdo this with lamentable consequences to the strength of the flue plates.—*Boston Journal of Commerce.*

Science in the Workshop.

The *Trade Review* says: "When mechanics as a general body become more thoroughly impressed with the conviction that the way to advancement, both as to personal position and monetary returns, lies through the mastery of science, in the application of principles to their daily work, we may anticipate some joint movement on their own part to establish means for acquiring technical knowledge. We might multiply examples of the benefit of courses of scientific training. The proper understanding of the laws of expansion and contraction, as applied to many castings, and even to the wrought-iron and steel industries, would prevent much waste in the foundry and at the forge, from the effect of unequal expansion and contraction, and also occasion fewer inequalities in the quality of that supposed treacherous material, steel. It would also prevent many mishaps to boilers, engines and their accessories in cold weather. A knowledge among workmen of the principles of inertia, as affecting bodies in motion, would frequently prevent a breakdown in starting or stopping machinery suddenly. For all connected with blast furnaces, the value of chemical knowledge is apparent, as enabling them to trace the cause of faulty results. There is scarcely a workshop of any importance, in which an acquaintance with geometry will not be of value. In short, the value of science asserts itself every hour in the workshop. The scientific mechanic never falls into ruts, either of thought or habit. Working more intelligently than others, he finds more pleasure in his labor. His suggestive faculties are ever at work, and he is ever alive to the possibility of mechanical improvements, from which he may reap a handsome reward. The manufacturers who have risen from the hench without acquaintance with technical science constantly feel themselves at a disadvantage.

EFFECTS PRODUCED BY HIGH PRESSURE.—EXPERIMENTS REPEATED.—M. Friedel, having questioned the announcement of M. Spring that a pressure of 5000 atmospheres exerted upon amorphous pulverulent matters causes them to become aggregated into crystalline masses, MM. E. Jannettaz, Neel and Clermont

determined to repeat his experiments, using pressures of from 6000 to 8000 atmospheres. They operated upon pulverized antimony, bismuth, zinc, iron, tin, copper and lead, Darcey's alloy and brass, lead, and zinc sulphides, iodine lead and mercurous chlorides, mercuric iodide, magnesia, alumina, silica, chalk, and copper sulphate. All these powders were agglutinated into solid masses, but even those which acquired some degree of transparency were not crystallized. Many of the substances, however, such as stearite, graphite, clays, and metals, acquired a schistous structure, and assumed the thermic properties characteristic of such structure.

INVENTIONS WANTED.—There will be no end to the number of inventions wanted until all the labor now performed by human hands is done by machinery. When all people can sit down and eat the bread of idleness—having nothing to do but watch machines performing all kinds of labor—then will come the day when cheap Chinese labor will no longer bother and vex the souls of the Knights of Labor. A recent number of *Mechanics* enumerates the following things for which there are loud calls: Macaroni-machinery, separators for mica and graphite, good red lead-pencils, comb-graining machinery, portable power transmitting dynamometer (preferably for helms), type-writers which will work on account books and record books, indelible stamp-cancelling ink, a practical car starter, a good railway car ventilator, better horse-shoes, radial car-axes, independent car-wheels, locomotive head-light, anemometer or instrument for measuring velocity of wind currents, apparatus for measuring the depth of the sea without sounding, by line, piano lid hinge which shall be "flush" on the outside, good fluid India ink for draughtsmen, reciprocation counter for locomotives, solder for aluminum, another good method of working iridium, substitute for coal-tar pitch in making artificial fuel from anthracite coal-dust and culm, good metallic railway tie, good independent cut-off for locomotives, flexible book back, method of alloying copper and iron, better facing compositions for iron-founding, good moulding material for iron and brass casting, capable of giving mould which can be used over and over again.

IMPROVED MODE OF DECORATING METAL SURFACES.—Mr. Piper, of Wolverhampton, England, has lately devised the following method of etching metallic surfaces, by which it appears possible to produce highly decorative effects.

According to Mr. Piper's method, the article to be treated is electro-plated with gold, silver, nickel, or other metal, and on this the design which it is desired to produce is traced with some suitable acid-resisting substance. The article is then immersed in an acid bath, by the action of which those portions of the surface which are left unprotected are deprived of their electro-plated coating, and the naked metal beneath is given a frosted or dead appearance. The article is then well rinsed to remove all traces of the acid employed and the acid-resisting varnish is removed by the use of alcohol, oil or other proper solvent. The result is a frosted or dead-luster surface of the original metal, upon which the design in the electro-plated metal stands up in relief. If, for example, the article be one of copper and the plating silver, the design will be in silver upon a dead copper ground. It is manifest that the operation may be reversed—that is, the design to be reproduced, instead of being protected, as in the foregoing procedure, may be left unprotected, and the remainder of the electro-plated surface covered. In this case, after going through the above described operations, the design would appear to be in dead copper on a silver ground.

EMPLOY ONLY THE BEST MACHINERY AND TOOLS.—In the present season of general depression it behooves machinists and manufacturers to exercise the utmost economy in every department of work, and especially in the character of the tools and machines with which they work. Every individual, indeed, should equip himself in the most efficient manner for the inevitable struggle for existence. How many firms are to-day using tools which should long since have been broken up and consigned to the furnace as old iron. Old firms are frequently seen holding on to antiquated tools through false ideas of economy, while younger firms are springing up all around and doing well because the older ones are heavily handicapped by their antiquated notions and practice. Take for example such a simple instance as a lathe, which is generally regarded by many as being pretty much the same thing all the world over; yet so great is the difference that, with the most modern tool, the same man would be producing 20 feet of 2½-inch shafting per hour, whilst with old ones, to which they still cling so tenaciously, he was scarcely able to produce 20 inches per hour. It is not sufficient now that a lathe should do a certain work, but it is also important that it should do that work in the least possible time. Many other instances might be noticed, but enough has already been said to suggest a few important thoughts to thinking men.

HOW TO USE FILES.—When you are doing a difficult filing job use two or three files. They seem to take hold better and work freer from having a "resting spell job." Perhaps it is because different files fit the hand differently, and thus furnish rest and a change.

SCIENTIFIC PROGRESS.

The Conservation of Energy.

We had occasion, a few days since, to step into the California Electrical Construction Works, on Stevenson street, in this city, of which Prof. N. S. Keith is electrical engineer. While examining the peculiar mechanism and construction of his dynamos, we were particularly interested in noticing the various forms of energy exhibited in those shops, and the ready and visible manner in which they were converted from one form to another. There was a line of shafting driven by an unseen steam engine. A belt from the shaft was driving a dynamo, which, in turn, exhausted its energy in producing several electric lights.

Here, in the first instance, was the stored-up energy of coal liberated in the form of heat, which was conveyed to the engine by means of steam.

In the second place, mechanical energy was seen developed by that heat and through the mechanism of the engine putting in motion shafts and pulleys which were connected with a dynamo, by which the mechanical energy developed was converted into electricity.

In the third place, we saw the electric current conveyed by a wire to a series of lamps and there disappearing, or rather being transformed, into light and heat.

The fourth step in the progress of this transformation of energy was the brilliant electric light, scattering its energy abroad, and piercing the surrounding darkness with its penetrating rays.

In this cycle of operations—this conservation and transformation of energy—not a single form came anywhere into existence without the disappearance of some other form. Heat was seen disappearing and mechanical energy appearing in its stead; next mechanical energy disappeared and re-appeared in the form of electricity, which, in its turn, disappeared only to re-appear the next instant as light and heat.

The conservation of energy was continuous and perfect. Nothing was lost—nothing gained. If instruments had been applied capable of measuring the amount of energy developed by the coal and followed throughout all its changes until its final disappearance in the heat and light of the electric lamps, making due allowance for friction, resistance and leakage in its passage, not a particle of energy would be found to have been lost. The great law of conservation of energy is perfect in its operation, and it is seldom that so rare an opportunity is offered for witnessing and studying this great economic law of nature as by a visit to the scientific workshop of Prof. Keith.

Echoes at Sea.

A new method of determining the near presence of icebergs on high shore lands and even ships in a fog, has been devised by Mr. Frank Della Torre, of Baltimore. This device is based upon echoes and has been thoroughly tested at Fort Carroll, by order of the Navy Department. This apparatus consists of a single harrel breech-loading rifle, provided with a large funnel or speaking trumpet on the muzzle, a box of cartridges, and a tripod. The first experiment was made from a tug, at a distance of half a mile from the fort. With the discharge of the rifle, a distant echo was heard by those on board the tug, without the use of any receiving apparatus other than the unassisted ear.

When a boat intervened between the tug and the fort, two echoes were heard, the fainter one coming from the vessel. In favorable weather, the echo has been heard four miles. The steam whistle of the tug was also tried, but gave less distinct echoes than the sharp report of a rifle. A passing steamer, about a mile from the tug, gave a very distinct echo. Mr. Della Torre's signal was intended primarily to prevent collisions with icebergs in heavy weather, when it was impossible to be aware of their presence except by means of an echo, but is equally applicable in advising a ship's officer of the neighborhood of another vessel or other obstruction to navigation.

Mr. Bell, it will be remembered, has interested himself in this method of signaling, and believes strongly in its practicality. The navy officers who made the experiments at Fort Carroll will report favorably on the invention, and advise further experimentation. It is suggested that an officer be detailed to try this method of collecting sound on board a United States man-of-war, so as to test the effect of different states of the weather, and ascertain precisely the range of usefulness possessed by the invention.

PHOTOGRAPHY BY A LIGHTNING FLASH.—From a communication by Professor E. J. Houston to the Franklin Institute, it would appear that Mr. Albert S. Barker, of Philadelphia, has succeeded in taking two very fair photographic negatives of outside objects while illuminated by no other light than that of a single lightning flash. These photographic views were taken at 7 p. m., while the night was excessively dark, the wind strong, and the rain heavy. The camera was placed in an open window, with the slide drawn. The lightning flash came in less than a minute, when the slide was returned. The plateholder was then reversed, and suitably placed for a second exposure. The plate was one of the highly sensitive

gelatine films. Mr. Barker developed the plates the same evening. From their behavior he estimated the actinic effect of the light to be equal to that obtained from an exposure of about 1-300 part of a second in bright sunlight. The popular impression as to the duration of the lightning flash is that it is practically instantaneous. From the experiments of Wheatstone and others with the rotating disc, the duration of the flashes measured would appear to vary from 0.001 to 0.0001 second. Others estimate the duration of the flash as even shorter than this. It is a significant fact that, in his photographs of Mr. Barker, the foliage shows unmistakable evidence of having perceptibly moved during the period of exposure, thus demonstrating that the flash was by no means instantaneous.

A Solar Cyclone.

Those who have looked through a large telescope under favorable atmospheric conditions, at one of those immense cyclones which occasionally break out on the surface of the sun, have derived from what they saw a very good idea of the origin of sunlight. They have seen that the brightest portion of the surface of the sun consists of columns of intensely hot metallic vapors, averaging about three hundred miles in diameter, rising from its interior and glowing with extreme brilliancy, from the presence of clouds formed, probably, of shining particles of carbon precipitated from its vapor as the tops of the columns reach the surface and lose heat by expansion and radiation. (A good idea of such a precipitation is had by observing the particles of water condensed from transparent vapor, in unusually high thunder-heads, where the action is in some respects similar). Between these ascending columns are seen descending masses of cooler vapors, rendered dark and smoky by relatively cool and opaque particles of carbon, all, or most, of the other elements being still maintained by the excessively high temperature in the condition of transparent vapor. In the immediate region, however, where the cyclones are raging, these bright ascending columns are drawn out horizontally by the rushing metallic winds (which often reach a velocity of a thousand miles per hour) into long filaments, pointing in general toward the center of the disturbances, which is always occupied by a huge black cloud of smoke (frequently twenty thousand miles in diameter) rapidly settling back into the interior of the sun. Over and across this great central black cloud are often driven long arms of the shining carbon clouds, which, when the cyclonic action is very strong, bend round into slowly changing spiral forms, very suggestive of intense action. A striking illusion, invariably connected with this sight, is that the observer seems to be viewing it from a position quite near the scene of the disturbance, whose minute and complicated details are seen with exquisite distinctness.—*Manufacturer and Builder.*

FORCE EXERTED BY GREAT STORMS.—Take the velocity of the wind at 60 miles per hour, or 5280 feet per minute, which is that of a violent storm, this pressure it exerts is one-eighth of a pound per square inch. Let us suppose further, that the breadth of the storm is 250 miles, and that the height of the storm wave is one mile. A square mile contains 4,014,489,600 square inches, so that for each mile in width of the storm there is a superficial area of 4,014,489,600 square inches, on which the storm acts with a pressure of one-eighth of a pound, and at a speed of 5230 feet per minute. From these data the equivalent horse power of a storm may be readily estimated, this result being 80,259,792-horse power for each mile of breadth over which the storm extends.

RESTORATION OF MAGNETISM BY HEAT.—A correspondent of the *Scientific American* says: "To heat a magnet to a red heat has long been known to destroy its magnetism; but from a recent experiment of mine with two sound magnets that have from want of care lost nearly all their magnetism, I fully restored them by rubbing a red hot iron, ¼-inch, over them until it had become quite cool. The magnets are now better than when new. This experiment was prompted in my desire to prove magnetism hears to heat as close a relation as electricity. Thus we hope soon to be able to make a clearer demonstration."

VITAL POWER OF MUSCLES AFTER DEATH.—Brown-Sequard, the French physiologist, has demonstrated that for several weeks after death, or during the persistence of the rigid condition which immediately follows the cessation of life, the muscles of an animal undergo slow, alternate contractions and elongations; and he reaches the startling conclusion that the muscles in *rigor mortis* are not dead, but are still endowed with vital powers, being, however, in a certain chemical condition which is antecedent and preparatory to final death.

THE AIR OF THE SEA.—The air of the sea, taken at a great distance from land, or even on the shore and in ports when the wind blows from the open, is in an almost perfect state of purity. Near continents the land winds drive before them an atmosphere always impure, but at 100 kilometers from the coasts this impurity has disappeared. The sea rapidly purifies the pestilential atmosphere of continents; hence, every expanse of water of a certain breadth becomes an absolute obstacle to the propagation of epidemics.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

AUTOMATIC RAILWAY SWITCH AND SIGNAL.—Edward Y. Kuapp, Arcata, Humboldt Co., assignor of one-half to George W. B. Yocum, of same place. No. 339,305. Dated April 6, 1886. This railway switch or signal is designed to be operated by an approaching train. It consists in an oscillating transverse shaft in the road-bed, a peculiar trip engaged by an arm on the locomotive, connections between said trip and the shaft, by which the latter is partly rotated, a weight connected with the shaft, and by which it is returned, a rotating lever connected by a pawl-and-ratchet mechanism with the shaft and operated thereby, balanced connections between said lever and the throw rails of the track, and the semaphore signal, and a pendant in the road-bed operated by the movement of the semaphore stem, and adapted to receive the contact of an arm on the locomotive whereby a bell is struck.

FRUIT-DRIER.—Andrew J. Hatch, S. F. No. 339,767. Dated April 13, 1886. This is more especially applicable to that class of fruit driers in which a long, horizontal chamber is employed having doors or openings at intervals on the sides, through which cars or trays are introduced to be dried, and removed when completed. It consists of a suspended, swinging or portable chamber, or casing, having its inner end fitted to rest against the side of the main chamber, so as to inclose one of the doors of said chamber, and having a door at its outer end which may be opened to admit a car and be closed behind it before the doors of the main chamber are opened; a means for making a tight joint between the edges of this removable chamber and the sides of the main chamber, and a means of transporting it along, by the side of the main chamber, so that it may be applied to any of the doors of said chamber.

HORSE HAY RAKE AND CARRIER.—Byron Jackson, S. F. No. 340,122. Dated April 20, 1886. This is an apparatus for gathering hay or grain and carrying it to a ricking or stacking apparatus or other point of deposit. It consists of a frame-work mounted on wheels, having long teeth or fingers projecting toward the front, a pushing and riding extension to the rear of said frame, with supporting-wheel hinged to said rigid extension, so that the rider may depress the points of the teeth by standing on the hinged wheel lever, until a load is gathered, when, by sitting on the stiff lever, his weight will raise the points and balance the load, and carry it on the wheels. It also consists in means for attaching horses to the frame or the extension independent of each other, so that they can steer the rake without a rudder or tiller wheel, and a swinging rack or frame suspended above the rear of the rake-teeth or fingers, having ropes connected with them and with the backing strap of the harness, so that the load may be discharged from the rake and in a compact mass. It further consists in tops or shoes by which the teeth or fingers of the rake are prevented from splitting or breaking, and in a means for holding hay or straw in place when being discharged from the rake.

LOGAN, Pahranagat District, Lincoln county, Nev., where some twenty years ago there were some 400 prospectors, is now populated by a singular character named Bythe, who ekes out a miserable existence by coyotting the rich ore from the ledge croppings of the district. This hermit owns, says a correspondent of the *Pioche Record*, some mines that in an accessible locality would make him a millionaire.

HARTSFELD FURNACE.—The *Tombstone Epitaph* of the 23d says: "The custom smelter started up yesterday under charge of Mr. Hartsfeld, the patentee. It made a successful run, showing that it is capable of doing good work."

THE Dayton, Nevada, News Reporter says: If present prospects hold good, and all expectations are realized, Dayton will presently come to the front as a bonanza town, the bonanza being the bed of the Carson river.

A RAILROAD from Fenner, on the Atlantic and Pacific, to the Pimelena mines, is to be built, and a smelter, to cost \$200,000, will be built at The Needles to work the ore from these mines.

THE Grand Central pumps are about completed and will in all probability commence operations in a few days. This will be good news to the Tombstone public.

THE last cleanup of the Young America mine, Sierra City, was \$29,000. The company employs about seventy men and has a twenty-stamp mill.

THE Auburn mine and mill near Dun Glen, Humboldt county, Nevada, has been sold for taxes, amounting to \$1054. The property cost the Chicago company owning it \$200,000.

THE 10-stamp mill belonging to Andrew Bros., on Hill's Flat, below the Idaho mine, Nevada county, was destroyed by fire last week.

USEFUL INFORMATION.

OVERWORKING BOILERS.—Doubtless much of the mystery of boiler explosions could be traced to the above-mentioned practice of over-weighting, a practice criminal in its nature, inexcusable on any grounds whatever. If the manufacturer needs more steam, let him get more boilers in which he can safely make the desired quantity of steam. To additionally load the safety valve is to test every part of the boiler beyond the safety point, and if an explosion does not result it is not the fault of the criminally careless engineer, or his principal the manufacturer. It is the height of foolhardiness to risk the lives of those engaged in the works or in the vicinity of the boiler, and to risk the liability of destruction of the buildings adjacent, simply that a few dollars may be saved or that a little more steam could be supplied than the safety limit in the boiler would permit. Some have the foolish idea that because a boiler has done good service for a number of years, it can be relied upon to perform duty beyond that prescribed by the rules of safety. They reason that because it never has exploded therefore it never will. But frequent explosions reported within the past few years should demonstrate that this view is erroneous. A due regard for the rights of others should deter a manufacturer from overworking his boiler, for, should an explosion occur, the lives and property of individuals residing in the vicinity will be imperilled. If the boiler is insured, then certainly such treatment of it as we have mentioned is a fraud upon the insurance company. But even were there no outside considerations, self-interest alone should teach the owners the impolicy of working their boilers beyond a safe pressure.—*Industrial World.*

LEATHERBOARD.—The manufacture of "leatherboard" as a substitute for real leather for shoe stiffening is an important industry in Maine. The peculiar thing about leatherboard is that to a certain extent the name is a misnomer. While the product has the color and quite the appearance of leather, yet the best qualities have no leather in their composition, but are composed, instead, of hemp, flax and similar materials, ground up and pressed into sheets by a somewhat similar process to that of the manufacture of paper. The manufacture affords a convenient opportunity for the disposal of old sails, cordage and other worn out materials into which the required ingredients have entered, and, as in the manufacture of paper, the product bears little apparent relation to any of its constituent parts.

BANK LOCKS.—As an illustration of the progress which has been made in the last few years in a single direction in the matter of material protection for the valuables of banks, it is interesting and important to note that the combination lock, which in its earlier stages was comparatively easily made a victim to Mr. Yale's wonderful micrometer, has now been so improved and perfected as to absolutely defy the searches of this little detector. Every bank cashier should remember one remarkable fact regarding the modern combination lock. If not properly looked after, regularly and thoroughly examined and cleaned, it will be liable to change its combinations. Instances where these locks have themselves changed their combinations have come under notice.

DISTEMPERING.—Whiting, and jellied size made into a paste, and then melted to a clear liquid, will, as most of our readers know, turn, to dry yellow, unless a little blue or black pigment be added, the mixture being afterwards strained. In applying the wash care should be taken to stop all draughts. The painter should face, as far as possible, the light so that his hand and arm should not shadow the end of each stroke. Care must be taken to have no patches requiring to be gone over. If the work is executed in a uniform dark tint inclining to blue, it will then dry white. The moment the job is finished the outside air should be freely admitted.

TO PREVENT DAMP WALLS.—A recent German invention, composed of pulverized iron and linseed varnish, is intended for covering damp walls, outer walls, and, in short, any place or vessel exposed to the action of the open air and to the weather. Should the articles to be painted be exposed to frequent changes of temperature, linseed oil varnish and amber varnish are mixed with the paint intended for the first two coats, without the addition of any artificial drying medium. The first coat is applied rather thin, the second one a little thicker and the last in rather a fluid state.

WATER-TIGHT BRICK.—A brick being porous as a lump of sugar, and having six sides, needs careful filling for water-tight work in cesspools, etc., and a thin grout of porridge of cement is commonly used. Heating the brick and soaking beforehand in thick coal tar has been recommended. A man may lay common wall all his life without learning how to make brick water-tight.

PAINT FOR WIRE CLOTH.—The *Scientific American* gives the following formula for mixing paint suitable for painting wire cloth green, one that will dry quick and hard and not easily crack off, and be glossy as if varnished. A

mixture of three-fourths zinc white with one-fourth white lead, to which a little drier has been added, will be found to answer quite well. Coloring matter to suit is ground in with the above. To mix and apply oil to prevent wire cloth from rusting by long standing, use raw linseed oil.

ZINC.—L. L'Hôte, in *Comptes Rendus*, says: As to the inquiry if zinc free from any foreign metals decomposes water either on boiling or in presence of dilute sulphuric acid, experiment proves that such is not the case. Pure zinc heated with distilled water in a flask, so arranged as to receive the gases over mercury, gives off no hydrogen on prolonged boiling, nor is it attacked by dilute sulphuric acid. The presence of iron in proportions of from 3 to 5 in 100,000 enables it to decompose water. Traces of arsenic and antimony have the same effect.

TEST FOR GLUE.—The following simple and easy test for glue is given: A weighed piece of glue (say one third of an ounce) is suspended in water for 24 hours, the temperature of which is not above 50° Fahr. The coloring material sinks and the glue swells from the absorption of the water. The glue is then taken out and weighed; the greater the increase in weight the better the glue. If it then be dried perfectly and weighed again, the weight of the coloring matter can be calculated from the difference between this and the original weight.—*Manufacturer and Builder.*

NEW GALVANIZING PROCESS.—A New England firm has introduced a new process for galvanizing wire. It is claimed that by this new method a thorough union of the coating with the body of the wire is secured, and that in every case a smooth, firm surface results. Great softness, tensile strength and uniformity of temper are also said to be obtained in the wire, while the coating itself remains intact after the wire has been tested by severe twisting.

TO KEEP CISTERN WATER SOFT.—Paraffine rubbed on the dry walls and bottom of a cistern and melted into the cement with a hot iron is the most effectual method of keeping the water soft or free from lime. Cisterns, when plastered with pure Portland cement, generally give satisfaction.

FOR A cheap preparation to dip wrought iron articles in to prevent rusting (after being milled), use hot soda water to clean from oil, then hot lime water, and dry.

GOOD HEALTH.

How to Live Long.

The *London Standard* says on this point: "Men or women who intend to be centenarians in these days must combine something of the old mode of life with something of the new mode of living. They must, while availing themselves of all the scientific discoveries and sanitary appliances of the age, imitate their grandfathers in the steady and tranquil habits that prevailed before the invention of locomotives and the telegraph. They must have their eight hours of sleep regularly; they must have intervals of repose and vacuity in the daytime; they must spend a goodly portion of their waking hours in the open air. Nor will that suffice; there will have to be regularity in the hours of their meals and discipline in the ordering of the dishes of which the meals are composed. We cannot believe that anybody will ever live to 100 who eats a heavy dinner every night of his life at eight o'clock. Champagne in abundance and Bordeaux and Burgundy are to be forsworn by persons who deliberately set before them the attainment of their hundredth birthday. Neither, with such an end in view, would the active life of a politician, a lawyer or a doctor be a sane enterprise. In order to reach that distant goal there must be a training, if not severe, at least regular and unflinching. Most of all, there must prevail in the existence of such a person, a tranquil serenity, an unruffled calm. Neither generous passions nor enthusiastic ideals must be allowed admittance. The pulse must never be driven up beyond a certain point, either by work, by anxiety, by fear or by hope. At the same time, mere stagnation will, in all probability, never enable a person to live to 100. There is such a thing as rusting out as well as wearing out. If a candle does not burn brightly enough it does not consume the wax with sufficient rapidity, and goes out for want of adequate combustion.

FOR DIPHTHERIA.—Dr. Wachsmuth, a noted physician of Berlin, recommends that the patient should first take as much warm tea or thinned milk as he can drink. The legs are then put for a long time in hot water, and afterward rubbed vigorously with the hand. The treatment is varied according to the stage of the disease by hot and cold rubbings and warm drinks. The patient is finally wrapped in woollens, and will recover if he can be made to sweat. Diphtheria is easily conveyed, and often by the most unexpected means. The Board of Health of Amsterdam, N. Y., have recently investigated an outbreak of diphtheria, from which two children died; a third, who was attacked, recovering. The disease was traced to a pet

kitten, with which a little girl played while the animal was sick with a swollen throat and discharge from the nose. The cat died. The child was taken sick and also died. Another girl had played with a doll which had belonged to the deceased child; she was also taken sick and died. Still another contracted the disease without other means of communication than the doll. The latter was supposed to have been disinfected.

A Sanitary View of Burial.

In a recent sermon the Rev. Dr. R. Heber Newton, of Mass., speaking of cremation, said: "Another custom which is wrongly conceived to be a duty toward the dead is that of interment as we now practice it. Our custom of disposing of the remains of the dead may be proper and necessary. It is not for me to dogmatize upon such a matter. To me personally the custom is unspeakably revolting. The earlier usages of interment facilitated the inevitable dissolution of the physical body, and made that process as speedy and inoffensive as possible. The old Greeks, when they buried at all, placed their dead truly in the bosom of earth-mother. They laid them away in the ground, draped in their flowing robes, flowers sprinkled above their breasts, nothing around them to interfere with the chemical process which nature immediately sets at work when death ensues, in order to return earth to earth, ashes to ashes, dust to dust. We have preserved the outward form of interment, and have then added every possible hindrance to the natural process of dissolution. We place our dead in two or three cases. We inclose the wooden casket in a metallic box and seal it as tight as possible. We cannot prevent the inevitable, but we can do what would be an innocuous process into one fraught with danger for the living. We would make the dead beneath the earth a standing menace to the living above the earth.

"So long as the population of a region is comparatively light, this danger may be insensible. As a district fills with the living, so it fills with the dead, and sanitary science can not save us from perpetual danger while the homes of the dead violate the laws of nature. The air will be poisoned by the gases that are liberated without the purifying influence of the chemical processes of the earth; the fountain-head of water will be tainted; the germs of disease will be turned up to the surface of the earth with every change that is made in our cemeteries. The time is coming very rapidly when we must face the sanitary problems involved in our methods of sepulture. Personally, I hope to see the introduction of cremation. For, seeking to use my life in some real, earnest work for my fellows, it would be grief to me to think that my remains became a source of danger to any human being who followed me upon the earth. No possible conception of duty towards the dead stands in the way of a reasonable solution of the problem of disposing of the physical remains of the dead. The forms of disposing of bodies are hut forms. By one way or another the inevitable process will be passed through, and the body will be restored to the common fund of nature, whence new generations shall draw the interest of life."

COLD WET WEATHER.—When cold weather is accompanied by much moisture in the air, it acts most depressingly on the nervous system of sensitive delicate persons. There are at least two reasons for this: one is the absence of the sun's rays and heat which act as powerful but healthful stimulants to the nervous system, keeping it up to a normal standard of activity; the other is the direct loss of bodily heat by a cold, moist atmosphere deprived of sunlight. Sensitive, delicate persons do not generally manufacture so much heat as others, and whenever it is abstracted by cold too rapidly the persons suffer great depression, and all the functions of the body are lowered. Circulation becomes defective, digestion less vigorous, breathing embarrassed, the muscles disinclined to action, and the nervous system deranged. Heaviness of spirits, gloomy views of life, listlessness and languor prevail. If such persons could be transported to a milder climate the load would be taken from them, and they would enjoy life. If this cannot be done, the best thing is to so far strengthen and harden the body and invigorate the will so as to become irresponsible to the weather.—*Herald of Health.*

BORAX AS AN ANTI-CHOLERA SPECIFIC, is recommended by an Italian physician, in doses of five or six grams—about 77 grains—a day. He believes that it destroys the microbes in the intestinal canal and even in the blood, and grounds his faith on the experience in seven contiguous borax factories in an Italian village during the terrible epidemic of 1884-5. The workmen in these establishments were quite free from the disease, which carried off a third of the inhabitants in and about the village.

HOW THE LUNGS BEGIN TO BREAK DOWN.—Dr. Curtis says: "In the ordinary healthy lung, perhaps even in persons who have a consumptive heredity, the germ which causes the break down of the lung may not be able to make an impression; but if the physical integrity is destroyed by poor food or any debilitating influence, or by a cold, then the germ is able to get in its work, and to multiply and produce its kind and to fill the lungs with tubercles."

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

MIDDLE BAR TUNNEL.—Amador Ledger: The rich strike in the big tunnel has revived the hopes of all concerning the future of this mining district. It seems that the point in the lower tunnel is over 600 feet vertical depth from the upper tunnel level and the strikes in the upper and lower tunnels are over 500 feet apart following the direction of the vein which pitches considerably to the north. What developments are in store in this unexplored space time alone can tell, but all the circumstances tend to prove that the two strikes are portions of the same vein. In the big tunnel, about 100 feet from the header, small seams of quartz mixed with black metal were encountered. These seams took a bend to the west, following the slate; the tunnel was continued in a straight course, and so the ore was lost until the slate was again struck last week. The same thing occurred in the tunnel above, and where the slate curved was found that the richest deposits of gold. It is believed that it will be found the same with the big tunnel, and that when the bend of the ore seam comes to be followed further and probably richer developments will be made.

QUARTZ MOUNTAIN.—This mine and mill has again been started up, after several months' work of preparation. It has been started up under the management of Messrs. Cummings and Jackson. Duncan concentrators have been put in at the mill, and they were started a few days ago, in charge of an expert from San Francisco sent up by the manufacturers. Considerable trouble is experienced in saving the sulphurets. They are so light and fine that in saving them a large proportion of sand is saved at the same time.

GOVER.—A fine body of rich ore was struck in this mine a few days ago, which has materially brightened the outlook for this property. We have not learned the dimensions of the new ledge.

MISCELLANEOUS.—A clean-up is being made at the Bartlett gravel claim at Slabtown. The present prospects are that it will turn out fairly. The South Spring Hill mine and mill were idle from Sunday to Wednesday. The stoppage was necessitated in order to put in the new reels preparatory to changing from flat to round wire cable for hoisting purposes. Everything was started again Wednesday. It is reported that a considerable advance on the million-dollar offer mentioned in our last issue for this property has been made. The Bunker Hill keeps 30 stamps running, but little improvement is apparent in the mine. Joseph Carrara is plodding along at the North California, working the rock at the Potosi mill. The quartz would pay pretty well, were it not for the frequent annoyances and stoppages caused by the breaking of some portion of the mill, which is old and worn out.

Mariposa.

SAXTON'S CREEK.—Mariposa Gazette, May 1: We learn through an informant who has visited the Schroeder, Diltz and other mines in the vicinity of Saxton's creek, that the winter's rain has developed extensive quartz ledges which were covered up with deep soil that has been removed by the force of the Little Giant and the water process. The Schroeder mine more particularly, which has a complete outfit of hydraulic machinery has been put to the test in washing down high embankments of dirt and some terrific slides, has exposed and laid open to view acres of what is called "blanket ledge," which lies at an angle of 30 to 35 degrees on the east side of the mountain overlooking Saxton's creek and the Merced river. What these extensive fields and masses of quartz are going to amount to will require time to tell. These flat blanket veins are rather a new feature in formation, as they lay piled up in various thickness, one on top of the other, to an unknown depth. The Diltz mine is the first that has shown rock of this character. With sufficient water some remarkable developments in mining would be made in this new section of country.

Inyo.

FURNACE.—Inyo Independent, May 1: The furnace at Lookout was started up for a run on Tuesday of last week. During the past two months or more Mr. Fitzgerald has been getting out plenty of good ore and the present run is liable to be the best ever made at the furnace.

CHRYSOPOLIS.—Work will be resumed at the Chrysopolis mines immediately. Mr. Chambers, brother-in-law of Mr. Bolinger, has authorized Mr. Eibeshutz to go ahead with the work and do all that in his judgment may be necessary for working the mines. Mr. Chambers himself will come here as soon as he can get matters arranged that now detain him at the Ontario mine, Park City, Utah.

NEW MILLS.—Register, April 29: We are informed that George Storey has new machinery on the way from San Francisco for a mill for the Poleta mine, to be erected just across the river from this place. He is a man to make the whole business a success. It is said the mill at the Casey mine will be ready to start up in about four weeks.

Mono.

THE STANDARD CON.—Bodie Miner, May 3: Report of Standard Consolidated Mining Company for the week ending Saturday, May 1st, 1886: Men employed 1; and about the mine: Engineers, 2; pumpmen, 1; shiftboss, 1; carpenter, 1; blacksmith, 1; miners, 25; stationers, 3; carmen, 5; timberman, 1; laborers, 1. Total employed, 41. The average of the ore bodies continue without change as regards both size and quality. Ore milled for the week 269 tons.

THE MONO.—Report for the week ending this date, May 2d, as follows: The southeast drift 700 is extended 20 feet. The west crosscut from south drift 700 is extended six feet. There were employed 11 miners, 2 carmen, 1 blacksmith's helper, and jointly with Bodie Con. 2 engineers, 1 carpenter, 1 fireman, 1 miner, 1 watchman, 1 carman, 1 foreman.

THE BODIE.—Following is the report of the Bodie Con. for the week ending May 2d, 1886: The east crosscut above 300 is extended nine feet. The Bodie north drift, 650 Mono, is extended seven

feet. There were employed three miners and one blacksmith, and jointly with the Mono, 2 engineers, 1 carpenter, 1 carman, 1 foreman, 1 watchman, 1 miner.

THE CON. PACIFIC.—For the week ending May 1st, we have to report an advance in the crosscut of six feet; making total length of drift 58 feet. The winze being sunk from the 135 foot level, on the Fortuna vein is now down nine feet in ground looking and working fairly.

Nevada.

THE COE MINE.—Grass Valley Union, May 4: The directors of the Coe Quartz Mining Company of this district have voted to set aside 40,000 of the 100,000 shares of the capital stock to raise a working fund to put up hoisting and pumping works upon the mine. It is the intention to use the money for building of works that will be run by water power from the South Yuba canal, the water to be brought in a ditch along the ridge north of the mine, and then emptied into a receiving works at an elevation of 240 feet above the works, to which a pipe-line will be laid and ample pressure obtained. It will be the present intention to work the mine down to the 4th, which is the lowest level opened, and is 304 feet from the surface, and in which there is a large extent of ground opened, but the shaft is down 200 feet below that, but no levels run. There is a large extent of ground opened, and when the shaft is pumped out to the fourth level it would be but a short time when the mine could be made to yield a large amount of ore. The mine formerly produced good ore, but it was not under skillful management, and the property which has always been considered good, has been permitted to remain idle many years until recently it has passed into the hands of the present company, who leased a portion of the ground above the first level, from which high grade ore is now being produced, scarcely any of the rock but what shows well in free gold.

THE BADGER.—Grass Valley Union, May 1: The machinery has all been placed at the Badger by Wm. S. May and Thos. Walker, who had the contract, ready for starting. The wheel wheel for running the mine is a six-foot Pelton wheel and the fall is about 60 feet, which will, it is thought, do the work of hoisting and pumping. The pipe will be connected with the works in about a week, when a number of men will be employed at the Badger.

YIELDING GOOD ORE.—The Orleans mill is running regularly on good pay ore from the Prescott Hill mine, which is extracted from the second level below the drain tunnel. The ledge is not large, but it is of excellent quality, having made decided improvement in the last two months.

San Bernardino.

A FINE PROSPECT.—Calico Print, May 2: Several months ago A. G. Rhodes and Geo. Plant went out prospecting and discovered some good prospects in the southeastern part of Death Valley, about 80 miles northeast of Calico. The district has been named Hope Springs, and the claim on which they are working, Black Metal mine. The mines are situated seven miles from a good spring. A shaft has been sunk fifteen feet, and the ore taken from the same samples well. Mr. Rhodes recently brought to the mill at Daggett 1,200 pounds of ore from the mine, the pulp assay of which went \$132.47 to the ton. From present indications the mine will yield considerable ore that will average \$100 to the ton. The belt in which this mine is located has been prospected for two miles and ore discovered at intervals its entire length. The owners of the group are A. G. Rhodes and Geo. Plant, who own one-third each, Mrs. Humiston and her nephew, Wm. Kelly, who own the remaining one-third. The owners of this new find are pleased with their prospects and will prosecute developments as long as they show up as well as at present.

Shasta.

IRON MOUNTAIN.—Shasta County Democrat, April 24: Operations at Iron Mountain have ceased for the present, all hands discharged and the mill shut down. We are informed that the cessation of operations is only temporary. Tom Green's five-stamp mill and double discharge battery arrived last week, as did also the five-stamp mill, single discharge battery, for the Brown Bear Mining Company of Deadwood, Schattuck & Shearer, who recently purchased the Reche mine near the County Hospital, have ordered hoisting and pumping machinery which they will place on the mine as soon as possible. The Texas and Georgia Mining Company's mine, at Old Diggings, was damaged by the late storm to the extent of about \$500, by the loss of four tons of sulphurets and the washing out of ditches and an ore dump.

Sisra.

BALD MOUNTAIN EXTENSION.—Mt. Messenger, May 1: The B. M. Ex. Co., of Forest City met with a little detention this week, owing to the breaking into the main tunnel of water which had accumulated in the old workings of the South Fork ground about 4000 feet from the mouth. When this ground was worked out and abandoned a drain was left, which, it was thought, would take all the water that would come from that source. It seems that this drain became clogged, backing the water up until it accumulated in such quantities over the main tunnel as to force its way down an old prospect shaft and into the tunnel. When it first broke in, it came in a perfect torrent, running two feet deep over the track for many hours. No difficulty was experienced in getting the men and animals out and all the injury, besides the delay was the covering of the track for quite a distance with soft bed rock. The timbers were not disturbed not even a spilling broken. A tunnel to connect with the old works was rapidly run, to tap the accumulated waters, and work was resumed.

Trinity.

A RICH SECTION.—Trinity Journal, May 1: Thanks to our friend C. W. Day, of Junction City, we had a pleasant ride to that town on Monday last. During Tuesday, we crossed the river on the great suspension bridge of the Hayes Red Hill gold mines, and visited the mine now being worked under the immediate management of Foreman J. R. Flagg. A great quantity of ground has already been worked this season, and much more will follow, as Canyon Creek from which their water supply is drawn is one of the best streams in the county. On the day of our visit the water was not turned on, as all hands were busy moving the giants and water-gates on the bed-rock nearer the banks. A brief examination of the side

ditches showed gold quite plenty—sufficient to indicate the paying nature of the ground already worked and to give promise of a rich harvest for the season work. Superintendent Benjamin is in charge of the works. From Red Hill we learned that more work was being done in the Bartlett & Evans, Leibbrandt and other mines than for several years past, and that they were paying fabulously. The same was said of Uncle Jo. Sturtevant's, Chapman & Fisher's and Sheridan Bros. mines further up the river. Cuth Given and Dave Sutherland have re-opened the mine on the point this side of Junction and will run it two or three months. Mr. D. A. Reed is making a success of his fluming operation in the bed of Oregon Gulch, having already struck bed-rock and so far meeting with much fewer obstructions and drawbacks than were anticipated when he commenced the undertaking. At the Gillivray ranch, Nick Lorenz is preparing to put in an elevator and open a mine near where the dwelling stands as the ground there is very rich. Fred. Hass, near the mouth of Oregon Gulch is working very rich ground this season and moving a great deal of it, his water supply this year being much better than for several previous seasons. On Oregon Mountain, Superintendent Loweridge is doing splendid work and making it pay better than ever; the present will prove a prosperous season for the Trinity Gold Mining company as well as for all others in that district. It is of course yet early to estimate with much exactness upon the product of mines, but enough has been done to show that all are paying well, and many thousands of dollars have already been cleaned up. The district within a radius of four or five miles of Junction City has more paying gravel than any other section of this county, and will this year produce not less than \$200,000 in the opinion of those who are in a position to know.

NEVADA.

Washos District.

HALE AND NORCROSS.—Enterprise, May 1: On the 2900 level the main lateral drift northward has been advanced 35 feet beyond crosscut No. 4, and is running in vein porphyry and low grade ore. A crosscut west from it will be started during the coming week into the main ore vein, which lies on the west side of this drift. The ore body developed in upraising and stoping above the 3100 level continues its excellent showing, and the good ore met with shows for itself. It is of the old-time granulated texture and rich sulphuret character, assaying up in the hundreds, and any extensive concentration of it will simply be a genuine bonanza, which the indications, both inherent and surrounding, promise the finding of in that vicinity before long, for, surely, where so much smoke is met with the fire cannot be far away. The best ore, met with in bunches, has been carefully selected and stored away in the lower drifts, waiting for an opportunity to raise it to the surface. During the past week this opportunity has been given by a cessation of advancement in the south lateral drift in Potosi, in order to put in drain boxes, and about 150 tons were hoisted to the surface through the Combination shaft, relieving the drifts considerably. More will be brought out as occasion offers, and in due time, when milling facilities shall be secured, the true bullion merits of all this ore will be satisfactorily ascertained.

POTOSI.—Only 15 feet of advancement was made in the main south or southwest drift on the 3100 level, owing to moist ground being met with in the face. It was deemed most advisable to stop and put in drain boxes throughout the drift from its connection with the Chollar. Should much of a flow of water be met with in a further advancement south crosscutting will be commenced in both this and the Chollar mine, cutting eastward into the main ore vein, along the west wall of which this drift has been run. A very short time now will decide this important proposition.

GOULD AND CURRY.—On the 600 level the main southeast drift continues advancing in vein porphyry, quartz and clay, showing some mineral. The crosscut west was suspended in a dry, hard porphyry formation, and a drift north started from it at an eligible point about 16 feet from where it left the main southeast drift. This is now running in porphyry and mineralized quartz.

CON. CALIFORNIA AND VIRGINIA.—About 400 tons per day continues to be the regular yield, the average value of which, according to battery samples at the Eureka and Morgan mills, being about \$14 per ton. Bullion worth \$41,000 has been shipped since last report. The exploration work on the 1400 and 1650 levels makes good progress, as usual.

CROWN POINT AND BELCHER.—About 350 tons is the present daily yield. The old ore stopes of the upper levels are holding out well, and an abundance of good milling ore is opened up by the explorations on the 1500, 1600 and 1700 levels.

YELLOW JACKET.—About 140 tons continues to be the daily yield from the old workings above the 1300 level. Exploration work goes ahead as usual at various eligible points, opening up more ore resources.

BEST AND BELCHER.—The pumps in the Osbiston shaft continue their effective work, and less than 75 feet of water remains to be raised in order to find the bottom of the shaft.

MEXICAN.—The main lateral joint Mexican and Ophir drift to the northwest is going ahead in regular vein material, and a new drift to the south has been started.

ALTA.—The main north drift, running now in Benton ground, has less than 100 feet further to run to connect with the old Lady Washington workings.

OPHIR.—On the 300 and 400 levels good, effective exploration steadily goes ahead in various eligible directions, with no important result to record.

KENTUCK.—The old upper workings give a steady daily yield of about 65 tons, the ore breasts and stopes looking and holding out well.

UNION CONSOLIDATED.—On the 500 level the crosscut east from the north lateral drift continues in vein porphyry, with some quartz and clay.

SIERRA NEVADA.—On the 520 level west crosscut No. 2 is now in 427 feet. Material, dry, hard quartzite and porphyry.

MONTE CRISTO.—Some ore is being extracted from the old mine for milling.

Bristol District.

TAILINGS.—Pioche Record, April 30: The roast-

ing of tailings at the Bristol mill has proven a perfect success. The only difficulty experienced is that the roaster is not of sufficient capacity; but now as it has proven a success, Mr. Charles Roe will construct a roaster of treble the capacity of the one now in operation.

Eureka District.

ANOTHER FURNACE.—Eureka Sentinel, May 2: It is said that the Eureka Con. Company will have added to their reduction works another furnace within 90 days, which will be used solely for the working of the speiss in their dumps.

RICHMOND.—The ore bins at the Richmond reduction works are full, and for the present no ore is being shipped down from the company's mine. It is probable two of the furnaces will be fired up about May 20th.

Esmeralda District.

AURORA.—Walker Lake Bulletin, April 28: Everything is moving along comfortably at Aurora. The result of work in both the Humboldt and New Esmeralda has been very encouraging, and the managers of the New Enterprise are very confident in the final outcome, being fully as good as was predicted in the start.

Hiko District.

PROSPECTS.—Cor. Eureka Sentinel, April 29: I had the pleasure of visiting Hiko not long since, and was agreeably surprised at the extent and richness of the mines. Among the most prominent are Gray Eagle, Buckeye, Twin Eagle, Baldback, Mono and Oohir. There are several patented claims in the district that are owned by New York and Chicago companies, but the owners prefer to remain passive until the advent of a railroad through that section. There are also several good prospects on Irish Mountain, among which may be mentioned the Vermilion. This claim shows a face of carbonate ore four and a half feet thick but will average \$40 per ton. The formation is lime, and the ledge croppings are over 100 feet in height. This ledge, in my opinion, will some day prove a bonanza, but at present it is not worth two bits to its owner, for even \$100 rock will not pay to ship from Hiko to Salt Lake City. From the fact that most of the ores of the district are pretty base and almost self-fluxing, the erection of a 20-ton furnace at Logan or Hiko would, in my opinion, be just the thing for that section.

Jefferson District.

MILL.—Belmont Courier, May 1: The little mill at Jefferson was started up this week. Bullion shipments will soon be in order.

Park Canyon District.

OPERATING.—Belmont Courier, May 1: The Giant Company continue to operate their mill and mine in Park Canyon.

Pennsylvania District.

FIRST BULLION.—Pioche Record, April 30: Three bars of bullion arrived from Pennsylvania District, and was valued at nearly \$3000. It is the first shipment ever made from that district, there having never been any works in the district until those recently erected by G. R. Barton. In early days the ore of that district was taken to Bullionville and reduced by the mills there. The bars contained about eighteen ounces in gold.

Pioche District.

BULLIONVILLE.—Cor. Eureka Sentinel, May 2: Bullionville is appropriately named, for there has been shipped from here during the rainy days of Pioche something in the neighborhood of \$12,000,000 in silver bricks. It will most likely be heard from again in the role of a bullion producer, the Godbe Company having erected one of the latest improved Stedefeldt furnaces for the chloridization of some 200,000 tons of tailings that assay \$12 per ton. This furnace, together with a large leaching plant, was set in motion a few months ago, but after a short run the company had to temporarily suspend operations in order to make some changes in the draught of the furnace, as well as to secure a competent manager, the party in charge having entirely failed to give satisfaction. Metallurgical experts are expected from Salt Lake, and as it was satisfactorily demonstrated by preliminary tests that the tailings can be chloridized and leached to a high percentage, it is safe to predict a success for the company. In a former letter to the Sentinel I predicted a success for Mr. Barton, who was then engaged in erecting a five-stamp mill on the old Klingensmith mine. I had the pleasure last evening of baving my predictions realized in the shape of three bars of bullion, valued at \$5,000, which is the proceeds of 17 days' run. Mr. Barton's confidence in the mine is such that he is going to add five more stamps to the mill, having enough \$50 ore in sight to run for several years. There are several other good claims in the district that only need to be opened to prove paying properties.

Spaulding Mining District.

A NEW DISTRICT.—Silver State, May 1: A letter received from Unionville says that a meeting of miners was held at Spaulding Canyon, and a new mining district was organized named "Spaulding Mining District." The south boundary of this district is on the divide between Sulphur and Spaulding canyons, and runs north ten miles to the divide north of Rockhill; east from initial point and north monuments five miles, and west five miles, making ten miles square. L. A. Purchett was elected District Mining Recorder, and F. Springer has been appointed as Deputy Recorder.

Tsm Pahuts District.

WORKING.—Cor. Eureka Sentinel, April 27: The mines of Tem Pahute, so far as developed, are unquestionably the richest of any camp in Southwestern Nevada, but in consequence of their isolated position, it being 100 miles to Pioche and 200 to the nearest point of railroad, very little has been done in the district. The principal mines of the camp are the Sterling, Standard and Legal Tender. From a disinterested gentleman who lately visited those mines I learn that the owners, Messrs. Smith, Service and Foucher, are at present working on the Sterling, formerly known as the Inca, at a point 150 feet from the surface; that the ledge is five feet of solid quartz between two well-defined walls, and that the ore as it is shot down will mill from \$80 to \$100 per ton. South and immediately joining the Sterling is the Standard, with one of the same character and quality. On the north lies the extension of the Legal Tender, with a ledge eight feet in

width that will assay \$50 per ton as it is shot down. One ton has been shipped from all three of these mines that milled over \$300 per ton. This is a pretty big showing, but when the fact is taken into consideration that \$100 ores are worthless to-day on the dumps at Tem Pahute, it is not so big for the poor men who have stayed with their mines for over 15 years. It is my candid opinion that with an abundance of wood in the mountains, and water which can be brought to within four miles of the mines by piping it four miles, Tem Pahute presents a rare opportunity for a legitimate company of miners.

TUSCARORA DISTRICT.

BELLE ISLE.—Tuscarora Times-Review, Apr. 30: North drift from east crosscut No. 7, 450-foot level has been extended six feet, No. 1 winze, 150-foot level, has been sunk five feet.

GRAND PRIZE.—North drift on the 200 level extended 20 feet. An upraise has been put up 19 feet above same level, and a crosscut run west 23 feet from the east lateral ledge. Stopos producing but little ore at present.

NAVAJO.—North drift on the east vein from No. 5 crosscut 350-foot level has been extended nine feet. South drift from Johnston crosscut has been extended sixteen feet.

ARIZONA.

SHIPMENTS OF RICH ORE.—Prescott Courier, April 30: With the opening of spring comes livelier times in Turkey creek and adjacent districts than we have seen for many months past. The chlorides are all hard at work in the different camps of Turkey creek and throughout the Bradshaw range, from the Goodwin mine to the Tip Top camp. Krunk Holler is the liveliest camp in this district, for the boys are taking out plenty of rich ore. Roberts & Given are driving a tunnel on the "Might Be," a strong vein of high grade carbonate ore. They have three tons ready for shipment which Mr. Given thinks will go \$400 per ton. The adjoining claim south—the Lookout—is owned by Powell. The claim looks well. One mile south of the Pine Spring mine, Alec Denny is working the Black Rattler. Mr. Denny has just shipped a large amount of ore from this mine to Socorro, and will make another shipment soon. McCann & Powell, on the Hawk-eye, have a large amount of high grade ore on the dumps ready for shipment. Morgan & Campbell, on the Wheel of Fortune, have several tons of high grade ore on the dumps, which they will commence sacking next week for shipment to Socorro. Herman Von Metz is running a tunnel on the Miners Star, a strong vein of chloride ore south of the Longfellow mine. Scarcity of sacks prevented Mr. Metz from making a large shipment last week. Tom Roach is sinking on the June Bug, a strong vein eight feet wide; the shaft is being sunk on the hanging wall. Mr. Roach will stop crosscutting to the foot wall this week; the ore is ruby and born silver. Ryan & Randolph will make their second shipment next week from their claim, the first south extension of the Roach mine—the richest mine in the district. Mr. Dawes made a rich strike in the Peck mine, on the level above the north tunnel. Harry Norton is chloriding north of the Peck, on Turkey creek, and making money. Ed. Gobin has 20 men at work in his gold mine in the Bradshaws. His mill keeps pounding away day and night. News comes from Walnut Grove that A. W. Callen is about to start up his mill in the Juniper Spring camp. Mr. Callen has very good property in that camp, adjoining which is John Mahoney's gold and silver mines, as rich and well defined mines as any in the county. We may look for lively times at Grizzle's camp this coming summer. Lester Jackson and John Curtin are working the War Eagle mine. They are fixing up the Bradshaw Basin mill, and will soon drop the stamps. The McKennin boys are taking out plenty of rich gold ore from their claim on the War Eagle, south of Jackson & Curtin. Frank Ryland and Dan Martin are fixing up camp in the Bradshaws preparatory to starting work on their gold mine.

GROOM CREEK DISTRICT.—Prescott Courier, April 30: Messrs. Kelly & Stephens and Mr. John Hutchins have leased their Nevada mine, for one year, to Messrs. Holaday & Raley, two thorough miners, who have tested the mine and feel certain of being able to take out of it a great deal of rich gold rock, which they will have worked at one of the mills on the creek. Lessees of the Kelly mine are stopping down good gold rock. The mill and concentrators are ready for work. Near Copper Basin, Frank Alters has just tapped the tunnel in the Catocin mine by a 60-foot shaft, and can now stoppe down as much shipping ore as he wants. The mine has paid from the grass roots, and will do tie to. Mr. Layton is shipping silver ore from his mine in Hasayampa district, and Frank Kuehne is taking very rich gold rock from a mine on Lower Lynx creek.

TOMBSTONE.—Democrat, May 1: The strike in the Uncle Sam, mention of which was made some weeks since, proves to have been by far the most important development that ever took place in that portion of the district. The Uncle Sam is owned by United States Marshal Meade and others, but is being worked under lease by the Harris brothers. It is an east and west location, one of its side lines forming the north end line of the State of Maine, the shaft where the strike was made being within 60 feet of the latter claim. The ore was encountered at a depth of 62 feet, in the bottom of a perpendicular shaft. The ore body, as at present developed, consists of a 12-inch streak or seam assaying about 1,200 ounces. No drifting on the ledge has yet been done, the lessees still being engaged in sinking. About 20 tons of this rich ore have been taken out. The ledge shows every indication of permanency. The owners and lessees are to be congratulated on their good fortune.

THE HILL MINES.—In conversation with Charley Leach, foreman of the Grand Central, a reporter of the Democrat yesterday learned that the pump rods are now in place, but the couplings have not yet all been made. Everything will be in readiness for starting by the 10th instant, and possibly a day or two earlier. The hill magnates are extremely reticent in regard to their future plans, and but little can be learned of a reliable nature. There seems to be a lack of harmony among the superintendents. It is well known that if the pumps handle the water successfully they will drain, not only the Contention and Grand Central, but also adjacent properties. Such being the case, it seems but fair and equitable

that the owners of these adjacent properties should bear their just proportion of the cost of operating the pumps. Many well-informed persons believe this question is accountable for the vexatious delays and apparent lack of energy displayed in starting the pumps. In fact, it is stated on good authority that negotiations are now pending by which a portion of the expense will be borne by outside companies. When this arrangement is perfected, which will probably be soon, the last impediment to a thorough exploitation of the mines below the water level will have been removed, and from that time will be dated the dawn of Tombstone's most prosperous era.

COLORADO.

ORE.—Georgetown Courier, April 29: A six-inch vein of apparently rich ore was recently encountered in the 300-foot level of the Bismarck. Morrison Bros., lessees on No. 5 lode, Columbia tunnel, are stopping a vein of nearly solid ore, from two to five inches in thickness. They are now above the level about 135 feet. A late mill run returned in two classes \$384 and \$151 per ton. The lessees on the Muscovite lode, Democrat mountain, have opened a vein of solid galena two feet in thickness. Dan Glaze on the A. T. Stewart lode, Democrat mountain, has a vein of solid ore which averages two inches in thickness, and mills from \$337 to \$340 per ton, in two classes. Ganley & Co.'s lease on the Pay Rock is said to be one of the best in the county. They are taking out an immense amount of rich ore, and making big pay. Cohen, Ganley & Co.'s lease on the Pay Rock is still turning out abundance of good ore. A millrun this week of about 20 tons returned between \$400 and \$500. Fred. Vinas & Co., lessees on the Algonquin lode, Saxon mountain, are pushing ahead the 160-foot adit. The breast shows a vein of quartz impregnated with mineral, ranging from four to eight inches in thickness. J. M. Charles, who has been crosscutting to the north wall of the Magnet, has reached it and found a good streak of high grade ore. The STL, ouis lode, Capital mountain, is being opened up with a good force of men. A drift has been run 48 feet. The breast shows a vein two feet thick which carries several small streaks of solid galena, ranging from one to two inches in thickness, which mills from 40 to 100 ounces silver per ton and 60 per cent lead. Johnson & Peterson, lessees on the Johnson lode, east Argentine, are drifting west from the bottom of the 40-foot shaft on a solid vein of ore from two to six inches in thickness. A shipment of three tons was made this week. McNulty, Noone & Co. have driven 130 feet east and 20 feet west from the bonanza tunnel on the Fred. Rogers vein, through barren ground. A raise is in progress to connect with the old workings. McTigue, O'Mara and Kane are stopping out six inches of solid ore, 50 feet below the McVeaty shaft. The last millrun in one class returned \$185 per ton.

IDAHO.

BANNER.—Idaho World, April 27: Mr. Brown, of the Elmira Company, says ore will be crushed in the Banner mill from the districts being opened up in the vicinity of Banner, in large or small lots. The company will crush even the small amount of one ton. If Silver district comes up to expectations, ore will be packed to Banner for reduction, and it is very probable that crushings will also be made of ore from Archie creek, and the Silver Chief Company will have ore crushed in the Banner mill. M. Kemper and another man from Banner went over to Silver district last week. Mat. Graham, Jr., returned with them. Mose says the tunnel running to tap the Julien location is in 193 feet. They expect to tap the vein in a few days, and at the depth of 250 feet. This location is owned by the Grahams. Twenty-one locations have been made in the district. Irwin and Austin have three or four fine-looking locations. Town lots and mill sites have been staked off and water rights taken.

SMOKE NOTES.—Ketchum Keystone, April 24: The King of the West, worked by two leases, one by Joe Montgomery in the upper works and the other by Wm. Mitchell and James Dougherty who have the main vein, is developing into the biggest bonanza in this upper country. Mitchell and Dougherty have a lease on the upper works, the provisions of which allow them 25 feet in depth on the ledge and 75 feet on both sides of their shaft, above which level they are entitled to a percentage of all ores extracted. In sinking, they struck the big vein at a depth of 20 feet and were compelled to stop sinking in sight of ten feet of the finest ore that ever was struck in such a body in the Wood River country. They are drifting and preparing to stoep out what comes within their limits, while the owners, Messrs. Geo. Montgomery, Geo. Black and Woodward, are arranging to put a large force on the mine at once. The Trade Dollar, another of the above company's properties, is likewise developing an immensely fine body of ore, several feet in width, and a bonanza itself, the characteristic of which is wire and horn silver, which is found in all the ore.

MONTANA.

MINING NEAR HELENA.—Independent, April 29: The country in the vicinity of Helena has long since become noted for mineral production and is still maintained by a number of unrivaled properties, the fame of which extends wherever mines or mining create interest. But besides these great properties there are a large number of smaller ones, either producing steadily or being developed into mines that will yet add to the wealth of Montana and of their owners. The Little Jennie continues to prove herself a fabulously rich property. From \$1,000 to \$2,000 worth of ore is being taken out every day in the course of development. Work is being pushed on both shaft and tunnel on the Mount Helena lode and the indications point to a certainty that the property will produce an abundance of good ore within thirty days. The first shipment of rich gold ore from Mr. Taylor's Cora lode arrived in the city yesterday. It will be followed by plenty more as soon as the roads become more easily passable. The developments in this mine make a fine showing of ore, and it promises to be one of the best in the gold belt south of Helena that stretches from the Whitlatch-Union to McClellan gulch. The owners of the rich gold find at the mouth of Big Indian gulch have got a fortune, if they stay with it as they unquestionably will. The vein is not very wide, but it is mar-

velously rich. The preparations for the opening of Trout creek and for sluicing New York gulch, across the river, are progressing rapidly. The saw mill for the purpose of cutting the lumber is expected to arrive at Helena this evening. When operations fully begin this camp will again be one of the booming camps of Montana.

BUTTE MILLS AND SMELTERS.—Inter-Mountain, Apr. 29: All the silver mills with the exception of the Clipper and Dexter, are running with a full supply of ore. The Alice has all it can do to crush the ore produced by the Alice and Magna Charta mines. The Moulton and Lexington mills keep their stamps supplied from their respective mines and from custom ores. The Silver Bow mill has twenty stamps dropping on Belle of Butte ore, and the other ten are also kept at work on ore from mines belonging to the company. The Old Lexington mill has all it can do to keep pace with the production of the Pacific mine.

THE SMELTERS.—The Parrot, Clark's Colusa, Colorado, and Butte Reduction Works are in full blast. There is not at present, nor has there been for a long time past, any want of ore felt at the smelters. Indeed there are some of the copper mines here that could easily furnish more ore to the smelters than they are just now willing to take, owing no doubt to the low price of copper.

NEW MEXICO.

COARSE GOLD.—Silver City Enterprise, April 23: Demerrick brothers brought in some very fine coarse gold on Tuesday which was panned out on Whiskey creek. The scarcity of water alone prevents Whiskey creek from being a lively placer camp. Chas. Osborne, one of the discoverers of the Old Man mine, came in from Pinos Altos this week. Charley has done 120 feet of drifting on the Great Western, and expects to strike the ledge in about twenty feet, when he can soon determine whether his time has been profitably spent or not. The Socorro Bulletin pays the following compliment to a Silver City man: Walter C. Hadley supersedes F. M. Endlich as manager of Sierra Grande Mining Company. Mr. Hadley was at one time editor of the Mining World and afterwards of the Las Vegas Gazette. He will fill the bill to a dot. Col. Adam Clark, the discoverer of the Great American mine in the Swiss-helm, Arizona, is in the city. Adam says that the property is looking well, and estimates that there is \$500,000 worth of \$20 and \$30 ore now on the dump, which, of course, cannot be handled at the present time, on account of the high expense of transportation. A well has been sunk on the company's property containing forty feet of water, the supply of which is thought to be inexhaustible. Our townsman, F. W. Graham, and his associate, W. G. Stegman, have secured a bond on the Forest King mine at Kingston, running ten months. This property was formerly known as the Grey Eagle mine, and has been in litigation almost from the day of its discovery until these gentlemen took hold of it. The first car-load of ore taken from the mine, returns from which Mr. Graham has just received, netted the owners \$1,058. The property will be worked regularly hereafter by a large force of men. This property makes the twelfth producing mine in the camp.

MAGDALENA DISTRICT.—Socorro Bulletin, May 1: The Grayhound continues to yield its supply of excellent fluxing ore. The Graphic M. & S. Co. are working the Review claim with good results, and will soon inaugurate an active regime in the Sampson. The Imperial is worked steadily and the ore is dispatched to Socorro for treatment. The property is admirably managed by Gen. Cook. Bob Huston and C. A. D. Conklin recently struck a large pocket of high grade argentiferous copper in the Mackay mine, Pueblo district. Supt. Huber is letting contracts on the Iron King mine, in Gallinas district to the lowest bidder, and also desires bids for hauling ore from that property to the terminus of the railroad at Magdalena. The Graphic smelter will blow in one of its furnaces next Tuesday. The maximum capacity of the plant when completed will be 120 tons per day. The three stacks will be in operation by the 15th of next month. The Kelly, the old solid stand-by of the camp, ships mineral constantly to the Billing works of Socorro. The exploitation of the property is steadily kept in view, and new bodies of ore reserves are reached from time to time. Col. J. S. Hutchison is working ten men on his Summit claim on the Magdalena range. The dimensions of his ore dump are enlarging rapidly, and he proposes to ship two carloads of mineral weekly from this property to Socorro for treatment. The Graphic mine is working 40 men, and the force is to be increased in a few days.

OREGON.

QUARTZ AND PLACER.—Jacksonville Times, May 3: Prospecting continues everywhere. N. Cooke informs us that the miners of Willow Springs district are cleaning up and generally doing well. Nothing new has transpired in this line since our last report, and mining items are consequently scarce. Placer miners are cleaning up, though some of them have enough water with which to groundsluice and pipe. R. Cook has commenced a new tunnel in the Steamboat district, as his old one has become so long that he cannot work to advantage in it. Swindon & Sons of Rock Point Precinct and Bell & Moody of Jackson creek are having several tons of quartz tested at the Jacksonville quartz mill. Messrs. Casteel and Huggins have almost completed the tunnel in Timber gulch for the Jacksonville Milling and Mining Co. It will be 160 feet long. Frank Logg offers his half-interest in first-class Placer mines on Jackass creek for sale, together with all the appurtenances belonging thereto. Here is a golden opportunity for the right man. J. Blalock and Geo. Owings have struck excellent placer diggings at the head of Jackson creek, and are making good wages with a limited supply of water. Geo. Blalock, who has been prospecting on Grave creek for sometime, has struck what he considers the best placer diggings in the state. They prospect exceedingly well. W. Coker, one of the California company who propose to inaugurate a big mining enterprise in the vicinity of Kerbyville, arrived there last week. Walsh & Bragdon are still pushing work on their quartz ledges on Wagner creek, where a tunnel and shaft are being run. A mess-house is being completed and timber

for the mill building is on the ground. The machinery Messrs. Brandt, Kehler and others proposing in there is expected to arrive soon. The outlook for this district seems to be favorable.

UTAH.

BINGHAM ORE SHIPMENTS.—Salt Lake Tribune, April 30: The old reliable camp of Bingham is making a better record than ever as an ore producer. Persons familiar with the condition of the mines say that the shipments of ore from this time till January next will average in the neighborhood of 5,000 tons of ore per month. This estimate is based on what is now ready to ship and the condition of the mines. For instance, the Yosemite is blocked up with between \$30,000 and \$40,000 worth of ore, awaiting the drying up of the roads so it can be shipped. Their tramway, which is one and one-third miles long, is about ready to start, and will be put to running in the next ten or fourteen days if some machinery arrives which has been ordered to complete this elevated wire rope tramway. It will have a capacity of nine or ten tons per hour, or over 200 per day, and its lower end being at a good place to load teams, it will greatly facilitate the shipment of ore to the smelters. Their new concentrating mill is located at the lower end of the tramway, and, being ready, will be started next week. It has a capacity of 40 or 50 tons of ore per twelve hour shift, reducing to about ten tons concentrates. This mill is so located as to be reached by the railway should the proposed branch of the Bingham road be extended there. At present more than one-half the ore product of Bingham district goes by wagons to the smelters, and the road is anxious to get the handling of this ore. To do this it is proposed to run a branch from Revere, seven miles below Bingham, around into Butterfield canyon, a distance of five miles. This would secure the carrying of ores of the Yosemite, Brooklyn, Queen, Lucky Boy, Old Telegraph and several other mines in that part of the district. The Old Telegraph mine, which failed to be profitable under the management of the French Company, is being worked by a half dozen or more lessees, and that hill is now like a bee-hive, with its many workmen. These lessees will send out several hundreds of tons of ore per month this season. The ore is being worked at the West Cottonwood works, owned by the French Company. The process is that of leaching, quite different from any other leaching works ever tried here before, and which is reported as successful.

REVIEW.—Salt Lake Tribune, April 30: The receipts of bullion in this city for the week ending April 26th, inclusive, were \$159,850.18; of ore, \$16,057.99; total, \$175,938.17. The receipts of the week previous were \$143,378.37, of which \$123,999.37 was bullion and \$19,879 was ore. The Ontario shipped for the week 69 bars of bullion, 43,662.21 ounces, but no ore, a severe snow-storm at the Park having interfered with ore shipments from the Ontario and other mines. The Daly output for the week was 8 bars of bullion—12,040.45 ounces. No ore shipments. The output of fine bars from the various mines, as per current reports, was for the current week, \$55,508; of base bullion, \$10,700. The Hanaer smelter produced during the week bullion to the value of \$29,780; the Germania, six cars of bullion, \$14,888.37; the Pascoe, \$1,750 in bullion. The Stormont sent up during the week silver bars to the value of \$3,340. From the Kentuck, on the 23d, there was received a gold bar—\$16,000. There is nothing from our Horn Silver, and the stock appears much less lively in New York than for some time past. Ore to the value of \$3,040 was received during the week; Queen of the Hills ore, \$4,680; Nevada concentrates, \$920; Overland ore, \$7,750; lead and silver, \$5,607.99.

PARK CROSSCUTS.—Park Record, May 1: Farish & McLaughlin have run a crosscut south from the bottom of their shaft about 15 feet and cut the vein; it is three feet wide, carrying high grade ore. This further establishes the courses of the great Daly vein to the westward. The adjoining ground westward that is sure to carry the vein is owned by Woodward & Bogan. The development on the Morey group still continues. Jim has just completed a crosscut to the north from his main tunnel and the lode has certainly cut the Ontario. The vein is nearly four foot wide and shows splendid ore. The Ontario ninth level at its eastern face is close to Morey's western boundary. This is a fine opportunity for men of some means to open a good property. The Deer Valley Con. Co., after a steady five months application of the pick and drill, has cut the first vein that was headed for with a tunnel, at a distance of 200 feet from its mouth. The vein is 10 feet thick of carbonate ore, high in lead and fair in silver. The company will soon commence the movement of ore to the market and the tunnel will be driven on to cut the copper producing vein that is known to exist at a point some 200 feet further in the hill. This property is well situated for mining, being one mile from the railroad depot with very little grade to the works. The Jupiter Company has kept a force of men developing their property all winter. At present the showing is good for a heavy output of ore during the summer months. The property is under the general management of C. L. Street.

SAMSON ITEMS.—Charles Read, a heavy stockholder in the Apex and Sampson, came up from Salt Lake last evening to look over the field of his operations.

CRESCENT.—The Crescent tramway will be opened for the transit of ores Sunday night, all the snow having been cleared off and repairs made to the track. Considerable ore will come down from the mine the coming week and about the 8th the concentrator will start up with facilities for getting away with large lots of ore.

DALY.—This morning the force at the Daly was increased, and operations will be henceforth prosecuted with great vigor. About \$40,000 worth of Daly ore will be received at the Mackintosh sampler this month. The Marsac mill is doing good work on the Daly ore, and during the last week its output was eight bars, contained 928 fine ounces of silver valued at \$201.

ONTARIO.—The mill is doing good work before being shut down for repairs, in about ten days. From the 24th to the 29th inst., inclusive, the Macintosh sampler received 653.80 pounds of Ontario ore. The shipments of bullion for the past week were 77 bars, containing 4,620,149 fine ounces of silver valued at \$45,277.47.

STURTEVANT MILL.

This Mill as a Crusher and Pulverizer is without rival. Is in operation in leading smelting works and mills.

END FOR CIRCULAR

IMPORTANT TO GOLD MINERS! SILVER-PLATED AMALGAMATING PLATES FOR SAVING GOLD

IN QUARTZ, GRAVEL AND PLACER MINING.

Warranted the Best Made, Durable and Satisfactory. Full weight of silver and best quality of plating guaranteed.

BEST SOFT LAKE SUPERIOR COPPER USED.

3000 Orders filled. References first class. Prices the very lowest. Have received every Medal awarded on the Pacific Coast for Mining Plates. Old Mining Plates Bought, Replated, or Gold Separated.

SAN FRANCISCO GOLD, SILVER AND NICKEL PLATING WORKS, 653 & 655 Mission St., San Francisco.
E. G. DENNISTON, Proprietor.

These Plates can also be procured of JOHN TAYLOR & CO., Dealers in Assayers' and Mining Material, 112 to 118 Pine St.

NOTICE.—Mining men are cautioned against purchasing inferior quality of Silver-Plated Mining Plates now being manufactured in this city. There has been a general complaint by purchasers that these plates proved defective in plating and short in weight of silver, assaying showing great deficiency in silver guaranteed. Thin, light plating looks the same as heavy, but has no durability. Good plates can be furnished at same price these poor plates cost.

CALIFORNIA ARTIFICIAL STONE PAVING CO.

(SCHILLINGER'S PATENT.)

—FOR—

**SIDEWALKS, GARDEN WALKS, CORRIDORS, OFFICES, CARRIAGE
DRIVES, STABLES and CELLAR FLOORS, KITCHENS, Etc.**

The Courts here and in the East have decided that Artificial Stone Pavements with plastic concrete and in detached blocks, are infringements on the Schillinger Patent; and also, that when the plastic material is blocked off with a trowel and cut through far enough to control the cracking caused by shrinkage, that such pavement is in law the same as if laid in detached blocks, and is an infringement of the patent. All property-owners having such pavements laid without the license of the above Company, will be prosecuted.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific States.

From the official report of U. S. Patents in Dewey & Co.'s Patent Office Library, 252 Market St., S. F.

- FOR WEEK ENDING APRIL 27, 1886.
- 340,556.—BOOT NAILING MACHINE—A. Cavalli, S. F.
- 340,861.—GATE—C. B. Clark, Williams, Cal.
- 340,699.—GRAFTING IMPLEMENT—O. H. Congar, Pasadena, Cal.
- 340,700.—GRAFTING IMPLEMENT—O. H. Congar, Pasadena, Cal.
- 340,868.—ELECTRICAL CUT-OUT—J. M. Fairchild, Portland, Oregon.
- 340,786.—APPARATUS FOR FEEDING WINE CASKS IN CELLARS—Geo. Johnston, S. F.
- 340,610.—STEAM AIR SHIP—Wm. Patterson, S. F.
- 340,676.—HOSE REEL AND IRRIGATOR—Jos. Perkins, S. F.
- 340,819.—STEAM ACTUATED VALVE—J. J. Reilly, S. F.
- 340,736.—WAGON AXLE NUT—F. O. Slanker, Pomona, Cal.
- 340,749.—MUSIC LEAF TURNER—L. L. White, Portland, Oregon.
- 340,847.—SCHOOL DESK—J. A. Wilson, Hood River, Oregon.
- 13,238.—TRADE MARK—North Shore Packing Co., Oakland, Cal.
- 13,239.—TRADE MARK—North Shore Packing Co., Oakland, Cal.

NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates and in the shortest possible time.

Mining Share Market.

The latter part of the week mining stocks showed an usual firmness and activity, with an advance in value that was refreshing to dealers after so much depression. The expressed opinions of mining magnates and experts who have recently visited the lower levels, amount to very little beyond the actual demonstration and developments made by the pick and drill. These have exposed a good large ore body in the upraising above the 3000 level, in which bunches of a high grade are found. The best of this ore has been selected and stored away in the lower drifts until an opportunity has at last been found to raise it to the surface, giving a much better chance to work in further explorations. The pumps at the Osborn shaft have been doing excellent work in reducing the water, and the prospects are that the bottom of the shaft will be seen in a very few days, after which sinking deeper will be the proposition. The low grade ore bonanzas at both north and south ends of the lode continue their regular bountiful yield, keeping hundreds of men and all the mills employed, and, although there is nothing new to report by way of encouragement, yet there is nothing particularly discouraging beyond the fact that the good prospects developed in the lower levels have not materialized into a veritable old-time bonanza as yet.

Bullion Shipments.

We quote shipments since our last, and shall be pleased to receive further reports:

Daly, May 1, \$9200; Ontario, 1, \$45,277; Alice, April 24, \$44,134; Moulton, 24, \$29,930; Lexington, 24, \$27,648; Silver Bow, 24, \$10,320; Moulton, 29, \$18,750; Marsac Mill, 24, \$9307; Germania, 28, \$2805; Hanauer, 28, \$5070; Queen of the Hills, 28, \$1750; Overland, 28, \$1750; Germania, 29, \$2757; Hanauer, 30, \$5050; Queen of the Hills, 30, \$2330; Germania, 30, \$3215; Hanauer, May 1, \$5870; Queen of the Hills, 1, \$2480; Germania, 1, 4921; Hanauer, 2, \$6810; Silver Reef (for April), \$33,439.

There was shipped from Salt Lake City during the week ending May 1st, 32 cars bullion, 772,876 pounds; 12 cars matte, 378,060 pounds, and four cars of ore, 137,000 pounds. The banks report the receipt for the week ending April 28th, inclusive, of \$159,880.18 in bullion and \$16,057.99 in ore; a total of \$175,938.17.

New York Metal Market.

Telegraphic advices dated May 7th, give the following New York prices:

BORAX—6 3/4 @ 7 1/4 c.

BAR SILVER—\$100 1/2 per oz.

COPPER-LAKE—\$11.37 1/2 @ \$11.50.

IRON—No. 1, \$17 @ 18; No. 2, \$16 @ \$16.50.

LEAD—\$4.85 @ 4.95.

QUICKSILVER—43 @ 43 1/2 c @ lb.

The following is the latest from the "New York Metal Market Report":

COPPER—Dull; Lake offered at 11.35c. Transferable Notices (Lake) offered at 11.35; Transferable Notices (Chili Bars) offered at 12.42.

LEAD—Steady at 4.75 @ 4.80c. Transferable Notices (Domestic) issued at 4.80.

SPELTER—Flat at 4.45 @ 4.70c. Transferable Notices (Domestic) issued at 4.50c.

TIN—Quiet and steady at 20.70 @ 20.85c. After 2d Call, 10 tons Straits May sold at 20.70c. Transferable Notices issued at \$20.70c.

TIN PLATE—Neglected. Transferable Notices issued at \$4.35.

IRON CERTIFICATES—Dull and unchanged. Transferable notices (May delivery) issued at \$17.

SILVER—New York, 100 3/4 per oz. London, 46 1/2-16d.

MAKER'S PRICES—At tidewater, 100 ton lots of listed irons (when brand is specified) range nominally about as follows: Lehigh, Grade No. 1, \$19 @ 19.50; No. 2, \$16.50 @ 17.50; Grey Forge, \$15.50 @ 17.00. Hudson River, Grade No. 1, \$18 @ 19; No. 2, \$16.50 @ 17.50; Grey Forge \$15.50 @ 16.50. Southern, Grade No. 1, \$18.50 @ 19; No. 2, \$17 @ 17.50; Grey Forge \$16 @ 17.

JAMES LEFFEL'S Mining Turbine Water Wheel.

These Wheels are designed for all purposes where limited quantities of water and high heads are utilized, and are guaranteed to give more power with less water than any other wheel made. Being placed on horizontal shaft, the power is transmitted direct to shafting by belts, dispensing with gearing.
Estimates furnished on application for wheels specially built and adapted in capacity to suit any particular case.
Further information can be obtained of this form of construction, as well as the ordinary Vertical Turbines for Wooden Penstocks and in Iron Globe Cases, free of cost, by applying to the manufacturers.

PATENT LIFE-SAVING RESPIRATOR

Entirely Prevents Lead Poisoning
and Salivation

The most perfect appliance for people engaged in Smelting, Dry Crushing, Guano Works, Quicksilver Mines, Lead Corroding, and all other occupations where there is dust, poisonous vapor, or bad odor.

In Feeding Threshing Machines, and similar work, they are indispensable, as no foreign substances can be inhaled when they are worn.
The Respirators are sold subject to approval after trial, and if not satisfactory the price will be refunded. Price, \$3.00 each or \$30.00 per dozen. Sent post-paid to any address on receipt of price.

IMPROVED FORM OF HYDRAULIC GIANTS.

The above cut illustrates the **IMPROVED FORM OF HYDRAULIC GIANTS**, which we manufacture. All similar styles are infringements upon this form, and a judgment stands of record to that effect, under the decision of Judge Sawyer of the U. S. Circuit Court in the matter of Hendy and Fishor vs. K. Hoskin et als.

Prices furnished upon application to

JOSHUA HENDY MACHINE WORKS,
39 to 51 Fremont St., San Francisco, Cal.

This cut represents our
**IMPROVED
HYDRAULIC
MACHINE.**

IT DIFFERS FROM THE OLD STYLE IN HAVING ONLY ONE JOINT instead of two. It is of greater capacity and more easily worked and kept in repair. The statement of Mr. Hendy that all styles are infringements on the machines made by him, he knows to be utterly false. All litigation has been in reference to old style two jointed machines, which are superseded by our new style one jointed. The decision of Judge Sawyer, referred to by him, is carried up on appeal to U. S. Supreme Court, with absolute certainty of a reversal in our favor. Send for Circulars and Price List.

THE ROLLER ORE FEEDER

(Patented May 23, 1882.)

This is the best and cheapest Ore Feeder now in use. It has fewer parts, requires less power, is simpler in adjustment than any other. Feeds coarse ore or soft clay alike uniformly, under one or all the stamps in a battery as required.

In the Bunker Hill Mill it has run continuously for two years, never having been out of order or costing a dollar or repairs.

HOOD'S FOUNDRY COKE.

Consumers are respectfully informed that owing to inferior brands of Cokes having been sold in this and other countries under the name of "Patent Coke," the Glamorgan Coal Co. (Limited), Cardiff, in May, 1884, abandoned the title of "Patent Foundry Cokes," substituting that of "Hood's Foundry Coke."

This Coke is exclusively used by the Selby Smelting and Lead Co., Union Iron Works, Professor Thomas Price, and other consumers here. Large quantities are regularly forwarded to Copper Smelters in Arizona and New Mexico, and also to consumers in Nevada and Salt Lake.

The undersigned are the SOLE IMPORTERS of the above Cokes, which is for sale in quantities to suit purchasers.

DEWEY & CO.'S SCIENTIFIC PRESS PATENT Agency is the oldest established and most successful on the Pacific Coast. No. 252 Market St., Elevator 12 Front St., S. F.

\$1,000 CHALLENGE!

**THE FRUE ORE CONCENTRATOR,
OR VANNING MACHINE.**

PRICE: FIVE HUNDRED AND SEVENTY-FIVE DOLLARS.
(\$575 00), F. O. B.

OVER 1,000 ARE NOW IN USE. Saves from 40 to 100 per cent more than any other Concentrator. Concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order and ready to make tests at the Fulton Iron Works, No. 220 Fremont Street, San Francisco. As the result of a suit East against an End-Shake Machine (the Embrey), similar to the Triumph, the Frue Vanning Machine Company owns the Embrey patent, and can put in the market an End-Shake Machine of earlier patent that will do as good work as the Triumph, and superior in construction and durability. There will be no risk of suit for infringement.

The Frue Vanning Machine Company warn the public that they claim and will prove the Triumph machine to be an infringement on patents owned by them.

Protected by patents May 4, 1869, Dec. 22 1874, Sept. 2, 1879, April 27, 1880, March 22, 1881, Feb. 20, 1883, Sept. 18, 1883. Patents applied for.

N. B.—We are and have been ready at any time to make a competitive trial against the Triumph, or any other Concentrator for a stake of \$1,000.

ADAMS & CARTER, Agents Frue Vanning Machine Co.,

Room 7—No. 109 California Street.

SAN FRANCISCO, CAL.

\$1,000 CHALLENGE ACCEPTED, PRICE, FIVE HUNDRED AND FIFTY DOLLARS (\$550.00).

**THE
"TRIUMPH" ORE CONCENTRATOR.**

This present improved form of this celebrated "TRIUMPH" Ore Concentrator possesses many advantages over any other style of Vanners, Vanning Machines, or Concentrators, yet introduced to the notice of mining men. These advantages consist in the superior features which enter into their construction, and facilitate their operation.

They are constructed in the best manner; their frames being of iron, insures their solidity, durability, and perfect steadiness of motion when operated. They are built as compactly as their requisites strength will permit, weigh less, require less freight space in boxes, by which their cost of transportation is reduced, and occupy less mill room when set up.

An important improvement has recently been introduced into their construction, which consists of a RIFLE TABLE, placed in front of and which takes the discharge from the feed and amalgam bowl. The improvement is in this reciprocal motion which is imparted to this table by the longitudinal motion of the shaking frame to which the table is attached. We have at hand many testimonials, from well-known Superintendents of mines in different mining districts of the United States, bearing evidence of the efficiency and superiority of this form of Concentrator, and we shall be pleased to send Circulars covering such letters of testimony, and, as well, directions for setting up and operating these machines, and are ready to quote special prices for any considerable order.

RANKIN, BRAYTON & CO.,
...BUILDERS OF...
MINING MACHINERY.

San Francisco: 127 First Street. Chicago: 100 N. Clinton. New York: 145 Broadway.

PLANTS FOR GOLD AND SILVER MILLS, embracing machinery of LATEST DESIGN and MOST IMPROVED construction. We offer our customers the BEST RESULTS of 35 YEARS' EXPERIENCE in this SPECIAL LINE of work, and are PREPARED to furnish from SAN FRANCISCO or CHICAGO, the MOST APPROVED character of MINING and REDUCTION MACHINERY, adapted to all grades of ores and SUPERIOR to that of any other make, at the LOWEST POSSIBLE PRICES.

We are also prepared to CONSTRUCT and DELIVER in COMPLETE RUNNING ORDER, in any locality, MILLS, CONCENTRATION WORKS, WATER JACKET SMELTING FURNACES, HOISTING WORKS, PUMPING MACHINERY, ETC., ETC., of any DESIRED CAPACITY.

WATER JACKET SMELTING FURNACES

For COPPER and ARGENTIFEROUS LEAD ores of NEW and ORIGINAL DESIGNS, covered by LETTERS PATENT. No other Furnace CAN COMPARE with these for DURABILITY, and in CAPACITY for uninterrupted work. MORE THAN 150 of them are now RUNNING in various parts of THIS COUNTRY, as well as many in FOREIGN COUNTRIES, giving results NEVER BEFORE ATTAINED as regards CONTINUOUS running, ECONOMY of fuel, AMOUNT and QUALITY of BULLION produced. These CLAIMS have been PROVEN BY RESULTS in ANY NUMBER of INSTANCES, and the GREAT SUPERIORITY of this SYSTEM of smelting ores, DEMONSTRATED BEYOND QUESTION. COMPLETE PLANTS furnished to order of any CAPACITY, with ALL IMPROVEMENTS that experience has DEMONSTRATED as VALUABLE in this class of work.

Beyond question the cheapest and most effective machine of the kind now in use adapted to all grades and classes of ores.

This machine has been THOROUGHLY TESTED for the past TWO YEARS, under a GREAT VARIETY of CONDITIONS, giving most EXTRAORDINARY results FAR IN ADVANCE of anything EVER BEFORE REALIZED. A recent COMPETITIVE TEST at the Carlisle Mine in Mexico, showed an ADVANTAGE OF OVER 30 PER CENT in favor of THE DUNCAN. The amount SAVED OVER THE FRUE being sufficient to PAY THE ENTIRE COST of the machine EVERY MONTH OF THE YEAR. One of its MOST VALUABLE features is as an AMALGAMATOR. It saves all the AMALGAM GOLD and SILVER that ESCAPES the BATTERIES, PANS or SETTLERS, making the machine worth MORE than ITS COST for THIS PURPOSE ALONE.

Baker's Mining Horse Power.

Possessing all the requirements of a first-class hoist and affording means for the continuous operation of a Pump or Blower, without interfering with a hoisting apparatus. It is made entirely of iron, no piece weighs over 300 pounds. At the ordinary speed of a horse, a 1,000-pound bucket of ore may be raised 120 feet per minute. The hoisting-drum is under the complete control of the man of the shaft, and is capable of carrying 500 feet of five-eighths steel rope. SEND FOR CIRCULAR.

Mining Compass and Trigonometer.

Almost every mining engineer who has had charge of underground workings will have observed how often directions as to course and levels, deduced from careful theodolite measurements, have been elighted and disregarded by mine foremen and shaft bosses, and how often their tedious measurements had to be repeated, even for minor works, such as ventilation drafts and winzes, in order to carry them on with the required or desirable regularity. Besides the time and care absorbed by theodolite surveys, there is still another inconvenience, namely, the interruption of transportation during the time of observation, and, in heavily producing mines, the loss consequent on such interruption.

In a recent paper read before the American Institute of Mining Engineers, Erich G. Gaertner, of New York, recommends to the consideration of American mining engineers a subsidiary instrument to the theodolite; not a new one but one which has been in use in prominent European mines for decades, and has there fulfilled its purpose admirably. This is the mining, or hanging compass, as shown in Fig. 1, of the engravings. Keuffel & De Esser, of New York, have lately constructed this instrument in a form which adapts it for better use in this country. By the addition of the trigonometer, the hanging compass becomes at once an instrument which will prove of value even in the hands of foremen and practical miners, who have little or no knowledge of trigonometrical calculations.

Probably many will say that we have no use for needle instruments; that our modern theodolites are of such perfect description, and leave so little to be desired, that the introduction of a compass would look like a step backwards compared to the fine results obtained by angle-instruments. It is not pretended that the accuracy of the hanging compass is equal to that of the theodolite, or even sufficient for close measurements.

But as an auxiliary, especially in irregularly worked mines, where frequent approximate surveys are desirable between the more formal and precise ones, it certainly has an important use. Even in mines where local attraction would affect the needle, it is not seen why the angle of two adjoining courses might not be taken by observing on both sides and close to the apex. The variation of the needle, under ordinary conditions, even if caused by local attraction, is likely to be the same, if the points of observation are but a few inches apart.

The hanging compass is constructed on the plan of a ship's compass, hanging level at all times, and giving the course by means of a stout cord from which the frame is suspended. The graduation is in quadrants, as in most theodolites, instead of the European division into hours; and the vertical arc, provided with a plumb-line, of fine silk, allows a direct reading to quarter-degrees and an approximation from five to ten minutes. The manipulation of the instrument (Fig. 2) is extremely simple: stretch a cord from brass screws fastened either in the timbering of the mine or in wooden bucks provided for that purpose, and read courses as well as vertical angles by suspending the compass and arc respectively from the tightly stretched cord. The co-ordinates to horizontal and vertical angles can be obtained by the other instrument mentioned, namely, the trigonometer. A

plate 15 inches square (Fig. 3), representing a division horizontally and vertically into 100 equal parts, which are again divided into halves, is provided with an arm or alidade, *AB*, which, having the same division as the plate, is fastened with its zero-point of the plate and moves freely around the same. A quadrant divided to quarter-degrees, and having this zero-

NICHOLIA, IDAHO. — Nicholia is a mining camp situated on the head of Burch creek, Lemhi county, Idaho. It is 75 miles from Camas, the nearest point on the railroad line. There are two furnaces, with a capacity of 40 tons, and two more will be put up this spring. There is plenty of ore in sight which runs 30 to 70 per cent lead and 30 ounces in silver per

Fig. 1.—HANGING COMPASS AND ARC, WITH CORD-SCREW AND CLAMP.

Fig. 2.—METHOD OF USING THE HANGING COMPASS.

Fig. 3.—THE TRIGONOMETER.

point as a center, is graduated upon the plate. By moving the arm to the given angle, and reading the distance of the respective measurements on the arm, the co-ordinates are immediately obtained on the plate, with sufficient accuracy for the calculation of measurements as obtained by the hanging compass. If, for instance, *BAC* is the given angle, and *AD* the given distance, *DE* and *DF* are the co-ordinates. Again, if *AE* be the radius, and *BAC* the angle of deflection, *DE* is the tangent, and so on, through all the trigonometrical functions. The readings are exact to within 0.1 per cent. A few hours devoted to the instruction of a foreman will enable him, if possessed of ordinary intelligence, to carry out measurements from the base lines established by the engineer, and save the latter much time, labor and inconvenience.

ton. The Spring Mountain prospects are looking well and are shipping ore of good quality to Nicholia. These facts we gain from a subscriber at Nicholia.

A PARTY of surveyors are said to be heading for a connection with the Atlantic and Pacific Railroad at Daggett, San Bernardino county, or Ludlow's, via Resting Springs, Coleman's borax works, and the Soda lake mines. They are very reticent, but many believe them to represent the Utah Southern Railroad.

A CRESTED BUTTE special to the *Republican* says: The shaft-house and concentrator of the Forest Queen mine, at Irwin, was completely destroyed by fire on Saturday night. The loss is \$30,000. No insurance. The fire is supposed to have been caused by an incendiary.

Tailings and Slimes.

In the treatment of tailings from silver ores with that class which is treated raw it is rarely possible to extract such a percentage as to render the tailings worthless, and therefore these are commonly saved and allowed to weather, salt being sometimes used to assist the decomposition. As a rule, however, there is enough salt remaining in the tailings after working the ore to produce the required effect in the course of a year or two. These tailing piles are, when possible, occasionally shoveled over so as to expose new surfaces to the air. It must be remembered that no matter how fine a particle of tailings may be, there can still be a particle of silver in the center of it, so completely enveloped by earthy material that chlorine cannot act upon it or quicksilver touch it. When tailings are treated only that portion of silver is amalgamated which is exposed to contact with the quicksilver. As the outsides of the particles have already been once subjected to the influence of chlorides and quicksilver, the amount of silver which can be recovered by a second amalgamation, of course taking it for granted that the ore was worked properly in the first place, is exceedingly small, except where long-continued grinding is practiced, or where the character of the gangue has been changed by machinery. The percentage extracted for tailings does not often exceed 50 per cent of assay value, and generally falls below this point. With the tailings from roasted ore, which are of lower grade than those from raw working, it is still more difficult to obtain the silver.

Slimes sometimes assay more than the ore itself, sometimes less. The percentage of slimes escaping from wet-crushing mills varies from one to fifteen per cent, according to the character of the ore. Ores containing much iron oxide generally produce the most slime.

Dichloride of Copper for Treating Ores.

A method of making dichloride of copper for treating ores has recently been patented, which consists in treating sulphate of copper in the presence of salt, water and metallic copper, under pressure and with heat. An ordinary metal cylinder is used, with the necessary pipes, cover and openings. In this are the necessary quantities or proportions of metallic copper, the desired salt—as chloride of sodium and a solution of sulphate of copper—that is, water and sulphate of copper. The head is then closed as are the faucets and discharge openings. Steam is then introduced and the mixture subjected to its heat and pressure. The inner surface of the cylinder or tank is lined with lignum vitae or other substance to resist the chemicals.

By the employment of the lining, for which the copper has no affinity, the apparatus is rendered capable of long-continued use, and successive withdrawals and renewals of the mixture may be made, so that a constant supply is furnished. The inventor, Mr. Abel Patchen, of Westfield, N. Y., does not limit himself to any proportions in the ingredients, nor to any particular strength of solution of sulphate of copper, nor to any particular degree of pressure. The product is designated "dichloride of copper," but the inventor does limit his invention by reason of the name, as whatever the product is designated, when produced by this process, it has proved useful in working ores.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

Squaw Creek Mines.

EDITORS PRESS:—Knowing how the PRESS devotes itself to promote the interest of mining, and keeps before the outside world the resources of the different camps, I have come to the conclusion that it is the duty of every miner not only to patronize the PRESS, but also to help it, through its columns, in letting the public know that the mining interests are neither dead nor secondary to any in the country. The gold quartz mining of the State is but yet in its infancy, and more good gold quartz ledges are being found to-day and opened up than ever before in the State.

With mining it is like any other business. If you wish it to be known and to prosper, you have got to place it before the public so they can see it, read of it and hear of it, and then they will commence to learn that California not only is great in wheat and fruits, but is equally as great a producer in that which goes not to exchange, but to add to the wealth of the world. A new mining camp that has the ledges and gold to back it does not want to be hushful about it, but let it be known. Write it up and let the journal which devotes itself to that special purpose spread it far and wide, and not place in black and white anything but what we are able to substantiate, so that when the capitalist whose attention it may have attracted comes, or sends his agent to look, he will see chances for good investment for his money, and that his trip is not for nothing. With this idea in view, I thought I would write to your paper and let the public know of a new gold mining camp that is just springing into existence and which is at the present time extracting from terra firma some of the "root of all evil" and sending it forth to be stamped with the bird of liberty and the goddess of justice and add more of the filthy lucre to the world. This new camp is known as "Squaw Creek." The mines were found about a year ago by Mr. J. Conant, and are situated about five miles from Kennet Station, on the line of the California & Oregon Railroad, twenty miles from Redding, in the old gold-producing county of Shasta. Although the camp is only a year old, there has been several good sales made: one of \$35,000 and another of \$15,000, besides various small sales of from \$1000, etc. There has been a road built into the mines, and although not a first-class one, still they have hauled in two mills, one a Gutenberg mill and the other a Huntington, which are running steadily day and night, and have every indication of doing so for years, judging from the piles of ore in sight in the ledges and veins. I will try and describe the district veins and formation in my next.

A. M.

Owners of the Big Bend Tunnel.

A Matter of History Corrected.

EDITORS PRESS:—Referring to the completion of the Big Bend tunnel, in Butte county, California, the *Oroville Mercury* refers to Major Frank McLaughlin as the great "prime mover" in that great enterprise, and states that to his energy and foresight the completion of that undertaking is due. In the interest of correct history, and in simple justice to others, please permit me space in your columns in which to make a few statements to correct the errors into which the *Mercury* has evidently fallen.

From papers now on file and in my possession I find that several old miners had projected this tunnel long before Major McLaughlin had anything to do with it, and were really the prime or original movers in this great enterprise. Subsequently, Mr. Geo. W. Cummings called the attention of Major McLaughlin to the property, and urged him, in letters now in my possession, to try and interest Eastern capitalists therein. But nothing seems to have been accomplished in that direction up to the time when my attention was first called to the property of Dr. W. Allstrom, then of Chicago, by whom I was induced to visit California, and by whose solicitations I purchased a one-fourth interest therein. Major McLaughlin, Colonel J. C. Logan, Dr. W. Allstrom and myself then each owned one-fourth interest in the property.

I then came East and organized the Big Bend Tunnel and Mining Company of this city, and with a friend of mine bought out the interest of Dr. Allstrom, and raised \$20,000 with which to defray the expenses of Major McLaughlin and Colonel Logan to go to Europe and endeavor to negotiate the sale of a portion of the property, in order thereby to raise the necessary funds with which to build the great tunnel. Their trip resulted in a complete failure, and we were thrown back upon our own resources.

Some time later I purchased the entire interest of Col. Logan and at different times for myself and friends, the entire interest of Major McLaughlin, with the exception of 150 shares, which now stand to the Major's credit on the

books of the company. The total capital stock of the company is divided into 200,000 shares. Over four-fifths of all the money to build the Big Bend tunnel has been furnished by me out of my own pocket, and the balance by friends of mine whom I induced to invest their money in this great undertaking. If any honor is due to any one for the building of this great mining work, it hardly seems fair, in view of the foregoing facts, that those who have done all the real work, and furnished all the money, should, on the completion of the tunnel, see another lionized as the "prime mover"—the man to whose "energy" the whole thing is attributed. I feel assured that Major McLaughlin claims no such distinction for himself.

The officers of the company feel that much credit is due Mr. N. A. Harris, our efficient superintendent, for his excellent and economical management of the company's affairs, as well as to Mr. John Cribbins, our tunnel foreman, and to the faithful men under them, for the completion of the tunnel with such remarkable speed.

The following complete list of all the present stockholders of the Big Bend Tunnel and Mining Company, who own 100 shares or more, with the number of shares owned by each, may be interesting and not out of place in substantiation of the foregoing statements. Very respectfully,
R. V. PIERCE,
President Big Bend Tunnel and Mining Co.
Buffalo, N. Y., April 29, 1886.

Hints for Lubricating.

EDITORS PRESS:—It is now known that one-half the power expended in mills and factories is consumed simply in overcoming friction. Such a fact ought to stimulate all owners of machinery to give attention to the purchase of the proper oils for its lubrication.

The trouble on this coast is that the oil bill is so small a part of the annual mill or factory expense that from year to year dangerous and destructive oils are used because they are cheap; or unnecessarily expensive oils are used because they have given no bad results. But large buyers who give the subject attention and take pains to ascertain for what purposes certain oils are useful, and for what others they are useless, annually make a saving in their oil bill that would startle the conceptions of the ordinary buyer.

It is not supposed that the average consumer of oil can take time to make elaborate tests or study coefficients of friction, but it is far cheaper to buy two or three grades of oil, each suitable to certain machinery, than it is to buy one expensive oil simply because it will lubricate everything without annoyance. The writer was recently sent for by a large mill where \$1.25 per gallon had been paid for an oil to lubricate the engine, when 45 cent oil would do the work just as smoothly and economically. Considerable indignation was expressed at the suggestion that the cheaper priced oil would do just as well, nevertheless the 45 cent oil is to-day lubricating that engine with perfect satisfaction.

To-day farmers on this coast enjoy the solitary distinction over farmers everywhere else of buying castor oil at from \$1.50 to \$2 per gallon for field work, when heavy blended petroleum lubricants do the same work at half the expense.

CHARLES J. WOODBURY.

BACK AGAIN.—A man who used to mine around here in 1851 returned the other day and is stopping at the New York hotel. He came back to prospect some rich places he used to know in the long ago. He thought he would find things pretty much as he left them, and in a year or so make a big stake out of the leavings of pioneer days. He is worse than disappointed at what he finds or rather what he fails to find. The mountains and streams seem to have changed with the people, and the ancient landmarks are missing. Things have got all turned around and misplaced, by some means, and the old prospector can't for the life of him tell where the rich claims are that he covered up and left behind him when he went back to the States almost a generation ago.—*Nevada Transcript*.

At Sutro Heights.

On Saturday, May 1st, President Holden, of the University, and a large representation of the faculty and senior class of the institution paid their respects to Adolph Sutro, Esq., at his beautiful residence by the sea, which is very appropriately named Sutro Heights. Mr. Sutro is an enthusiastic patron and promoter of the arts, and the higher branches of learning, and it was very fitting that the working forces of the University should show their respect for him in the manner stated.

Sutro Heights is an estate exceedingly beautiful for situation. As one stands upon the esplanade which Mr. Sutro has carved from the native rock and set about with statues from the home of art beside the Mediterranean, one can but harbor the thought that intellectually, as well as otherwise, the course of empire has really taken its way westward until the placid waters of the Pacific declare its journey done. It certainly is a fitting enterprise to crown a life of great action to undertake, as Mr. Sutro has done, to establish upon the very cliffs of the ocean a retreat clad in the beauties of tree and shrub and flowering plant and enriched by treasures of art and literature gathered from the best sources of the world. It is the wish of all who know his plans that many years may be spared him to complete his work and to enjoy it.

Judged by the aims which Mr. Sutro has to develop and improve his seaside home, his enterprise is little more than begun; but viewing it as a cursory visitor would, it seems already complete and delightful. Certainly during this last few years wonders have been accomplished. Over the sands which pertain to such a littoral situation, there is now a garden of several acres which for thrift and beauty of individual plants and general landscape gardening effects, would put to the blush many a site where the owner has naturally rich soil and natural shelter for his allies. More than this, there is a profusion of statuary art, embodying all modes of human thought from the magnificent winged Apollo which crowns an eminence and the stately Minerva, linking the achievement of intellect with the joys of domestic life, down to the nymphs which nestle in the shade and the tiny grotesques which seem to be gambling on the grass plots. It would be wholly impossible to give any sketch of the richness and variety of the Heights in these regards. One could spend weeks in contemplation of the masterpieces here brought into close association within a stone's throw of the sounding surf of the Pacific.

We have said Mr. Sutro has but begun his work. This is shown by the millions of seedling maritime pines, and Monterey pines and cypresses which he has in his nurseries, not to speak of the wealth of hedging plants in the propagating frames and plant houses. Suggestions of efforts to come are also seen in the huge cases of tiles and slabs and blocks of stone which he has brought from abroad to weave into his structures and outdoor improvements. His spacious residence is overflowing with rare art and bric-a-brac, and down in the city he has large collections of manuscripts and perhaps 100,000 volumes of valuable scientific and literary books—a contribution of inestimable value to intellectual culture on this coast. It is this rich possession which Mr. Sutro proposes to establish on Sutro Heights and thus make it available to eager students. It is his plan to construct a fine building according to his own designs which will contain the library and abundant room and conveniences for those who desire to pursue special studies and investigations.

Naturally this design awakened much interest among the University visitors and their appreciation of Mr. Sutro's valuable plans in this direction was earnestly expressed. President Holden assured Mr. Sutro that the facilities which he was preparing for scholarly work would be regarded with keen interest and the fullest fellow-feeling by the University people, and that the closest relations with his library would be courted, for it would be of inestimable value in many departments of University effort.

But we cannot follow a pleasant and profitable day at Sutro Heights to greater length at this time. Mr. Sutro entertained his guests royally. The visit was certainly a delight to all who joined in making it.

IS THIS CORRECT?—By reason of the collection of ores of many grades in richness and quality and mixing them, to produce the proper fluxes, enables the smelters at Salt Lake City to pay good prices for ore. The present charges for reduction range from \$6 to \$18 per ton, according to character, says the *Tribune*, and the result is that ore comes here from Nevada, where, if milled, would be from \$20 to \$25 per ton, and the mill's only guarantee 80 per cent of the assay value, thus bringing the net yield of \$100 ore down to \$55. Here the smelters deduct only five per cent for loss instead of 20, as the mills do, while the charges are from \$5 to \$10 less. This fact is bringing hundreds of tons of Nevada ore to this city, and the amount is all the time increasing, thus making that State an important field to draw supplies of ore from.

THE tricycle has been adopted for the postal service in Stuttgart, Germany.

New Gold Fields.

E. L. Baker, our Consul-General at Buenos Ayres, has recently reported to the State Department the discovery of gold in Patagonia. According to the report of the commission appointed by the Argentine Republic to examine these deposits they are of superior class; and "there is abundance both of gold and platinum." Mr. Baker says the ore is believed to be richer than that of California or Australia. Not the least interesting fact about this discovery is that the new gold fields are easily accessible. The deposits are said to extend from Cape Virgin, on the northern shore of the straits of Magellan, through which many vessels pass every year, northward along the Atlantic coast for 40 or 50 miles.

Among the mining companies organized last year in London were 14 projected to carry on operations in the gold and diamond fields of South Africa, three companies for Asia, 12 for South America, six for Mexico and Central America and five for Australasia.

Among the mountains and foothills that border the southern and western frontiers of the Transvaal hundreds of miners are developing placer diggings, from which during the closing week of last year 2550 ounces of gold were received at Natal. In the same region an Englishman is now turning out several tons of lead a day. The civil engineer, Anderson, reported 15 months ago that among these same ranges of hills west and northwest of the Transvaal there were rich deposits of gold. He said the natives as yet would not allow the country to be properly prospected, but that if the region were annexed to the British crown there would be no difficulty in developing its resources. This country is included in the great distance over which Great Britain, by treaty with the native chiefs, assumed a protectorate last year.

Still further north, among the many southern affluents of the Zambezi, W. Montagu Kerr recently found rich indications of gold. He brought home from these sandy river beds numerous specimens, generally free from base metals. He says the natives wash the alluvial deposits in wooden trays, and put the gold they extract in large gulls, which they carry great distances to trade for cloth and ornaments. A part of this gold-producing region had never before been visited by a white man, but in another part the Portuguese formerly carried on profitable diggings, though their methods of mining were cumbersome and expensive. It was these mines, together with the ivory trade, that made Tette, far inland on the Zambezi river, at one time a busy and important town.

Prejevalsky, the explorer, is now telling the Russian audiences to whom he is describing his last great journey that "gold is very plentiful throughout Northern Thibet." He says he saw natives mining near the sources of the Hoang Ho river. They dug only one or two feet below the surface, and their methods of washing were of the most primitive description. "Nevertheless," says Prejevalsky, "they showed us whole handfuls of gold in lumps as big as peas, and twice or thrice as big." W. Mesny, who has also visited the diggings of Northern and Eastern Thibet, corroborates Prejevalsky's estimate of their great value. He says he saw gold in nuggets from the size of a pea to that of a hazel nut, almost perfectly pure and perfectly malleable. Prejevalsky expresses the opinion that at a lower depth great treasures will be found on this immensely elevated plateau. The deepest and richest diggings observed by Mr. Mesny were about 16 feet below the surface. In his opinion no metal will be found below the bed of rock on which this surface gold-bearing stratum rests, and in this respect he appears to dissent from the opinion expressed by Prejevalsky.

The discovery of gold two years ago in Manchuria was another of the numerous sources of unpleasantness between Russia and China. As the diggings were only twenty miles from the Russian possessions, a number of Russians joined the Chinese and Koreans who were there washing gold. One feature of the resulting disturbance was a skirmish between Russian and Chinese troops in June last, and then, it is reported, the intruding miners, with Russia's consent, were hustled out of the forbidden territory.

From Madagascar and Honduras reports have been received of new discoveries of gold. An expedition from the Argentine Republic is now supposed to be ascending the Chabut river in Patagonia to see if the reports derived from Indians, that gold is found at its headwaters among the Cordilleras, are true. Many of these regions are still practically closed to white men, and the golden promises of some of them may never be realized. The big nuggets found in Tasmania, a few years ago, caused a rush to her gold fields for a while, but to-day, although the annual gold product of that island amounts to \$1,200,000, only two among 160 mining companies are paying large dividends.—*New York Sun*.

SINGULAR EXPLOSION.—A singular explosion occurred in the hardware store of Rutherford & McPike, at Vallejo, last week, from an empty paint barrel that had remained in the store for several years where the sun shone through a skylight upon it, and it being air-tight, coated on the inside with paint, generated gas, and when it was struck, with the intention of breaking it up, an explosion followed which was heard for blocks round. Fortunately, very little damage was done.

Rural Health Retreat.

MESSRS. EDITORS:—Having spent about three months at this health resort, I would like, with your consent, to say a few words to the public concerning it. Perhaps I may be able to assist some health-seeker in finding the home and health he needs. I am the more inclined to do this from the fact that the place is little known. It is not included in the catalogue of numerous pleasure resorts and sanitary watering places in the State in the San Francisco Hotel Gazette. Then the proprietors seem rather shy about tooting their own horn. The hen cackles over her newly laid egg; the stump orators and statesmen speak to the reporters; preachers advertise the topics of their sermons, especially when they think they have a bit of something good. Why should the doctors and hygienic philanthropists hide their light under a bushel?

The institution known as the Rural Health Retreat was first founded in a private enterprise by W. A. Pratt, A. B. Atwood and M. G. Kellogg, and chiefly intended as a pleasure resort and restful retreat, but not proving a remunerative investment, was subsequently transferred to a corporation composed of leading Adventist brethren, and has ever since been recognized as an adjunct of the general cause. It is run pretty much on the same plan of the celebrated Battle Creek, Mich., sanitarium. The brethren of this society have evidently been very liberal in their contribution to this worthy enterprise. The present officers are: J. N. Loughborough, President. The Board of Directors comprise the following well-known persons: M. A. Pratt, J. N. Loughborough, J. D. Price, J. H. Waggoner, M. C. White, A. B. Atwood and Wm. Ings.

Ex-Senator Matt Carpenter, on taking a drive over Chicago and surroundings, exclaimed, "Surely the Lord meant business when he made this country." This excellent institution is evidently located along one of the divine parallels of health and beauty. It is situated on the southwestern slope of the Napa mountains, about two miles north of the bustling village of St. Helena, in Napa county, California. It is about 1200 feet above the level of the sea, quite above the range of the fog currents. The air is pure and bracing and has proved to be a specific for malaria, catarrhal affections and troubles of the throat and lungs. The Crystal springs, a few steps above the Retreat, furnish an abundant supply of the purest, soft water. Many eminent medical men have pronounced the water from these springs far superior to any other for the purpose of life and health. There is no superior winter resort for invalids in the land. Here the verberna, geranium, and a great variety of other flowers bloom in the open air during the winter months. As a summer resort it is especially inviting to invalids as the variation of temperature is considered as favorable as at any other locality in California. And then one never tires gazing at the picturesque landscape from the piazza of the Retreat. Emerson says Nature gets up such magnificent sunsets because she has been so long trying. She must have been in an unusually happy mood when she shaped these hills and dales. Below is the Napa valley dotted with orchards, vineyards, gardens and homes that have an air of thrift, plenty and content. On the opposite side of the valley looms up the Sonoma range of mountains, covered with vineyards, interspersed with oak groves, clumps of the scrubby manzanita, the madrona, crowned with pine and fir.

The curve of this range shelters the Retreat from the chill, raw atmosphere of the coast and breaks the force of the winds. To the north may be seen the famous Mt. St. Helena, standing as a grim sentinel at the head of the valley, with its volcanic-scarred head often hidden among the clouds. The mountains in the immediate vicinity of the Retreat are clothed with evergreen shrub trees and an endless variety of wild flowers that fill the air with their sweet fragrance. These hills and slopes furnish delightful walks and rambling grounds. So charming and varied is the scenery and bracing the air that invalids are often tempted into over-doing.

The medical board consists of Drs. J. S. Gibbs and W. P. Burke. These gentlemen are amply equipped for their work both by education and experience. Their success is simply marvelous when we remember that their pa-

tients are mostly chronic cases that come here as the last chance. During our long sojourn we never knew one leave this infirmary that was not thoroughly cured or greatly improved. Hot and cold baths of every description are given, together with an intelligent use of electricity, faradio and galvanic, Swedish movement, massage and the vacuum treatment. Special attention is given by these medical attendants to all available hygienic agencies for the recovery of the sick. While not cranky vegetarians and Grahamites, they eliminate from the table as hurtful many dishes that are in ordinary use. The meat into which the devil went and out of which there is no proof they ever came is held in especial disfavor.

One of the first things the visitor notices on coming here is the air of sociability that pervades the place. In an hour's time he feels perfectly at home. He finds no one afflicted with homesickness. The affable superintendent, J. D. Rice, the ever watchful and sympathetic matron, Mrs. J. S. Ings, the vigilant doctors, and indeed, all the officials and helpers seem to vie with each other in making the sojourn of the invalid pleasant and comfortable. And this is not the studied and artificial politeness of hotel officials and waiters, but is something akin to the spontaneity of humanity. But what is still better, the Retreat is in the hands of men who revere God and devoutly prize the principles of morality and religion. One cannot help feeling that he is in a pure moral atmosphere, that it is spiritually healthful, and that he can recommend to his friends to send wife or daughter here without fear that their sensibilities will be shocked by ribald jokes, bad manners and exhibitions of intemperance and profanity.

The original building has recently been thoroughly refitted, and an extensive addition is nearly complete. The snug cottages are admirably adapted to the use of families. The croquet ground, swings, swinging chairs, hammocks, rustic seats and benches under the shade trees, all add to the health, enjoyment and pleasure of the invalids and other boarders. The terms for board, room and treatment are very reasonable. If these lines should be the means of leading any health-seeker to this resort, he will never regret it; and the writer, who has no interest whatever in this institution—only goodwill for a noble cause—will feel that he has at least cast one crumb of bread upon the waters. W. W. McK.

Quartzite Ore Deposits.

A great many persons consider the ore bodies in the quartzite at Red Cliff an anomaly in ore deposits. While the occurrence of ore in quartzites is rather unusual, Eagle River quartzites are not the only ones so far discovered, that have proved profitably productive. The Old Man, and other mines in the neighborhood of Camp Fleming, near Silver City, New Mexico, are analogous. Both are secondary depositions of silver formerly contained in a vein situated between the overlying limestone and superincumbent porphyry. The mineral in the Red Cliff quartzite was unquestionably liberated from the limestone-porphry contact, which at one time extended across the Eagle River canyon, and well up on Girard mountain, possibly to the foot of the Mount of the Holy Cross. All this area to the southward of the canyon now presents the appearance of a great tilted meadow, the carboniferous limestone and overlying eruptive rocks having all been scored away, down to the adamant quartzites, which interrupted the course of disintegration and erosion. The area denuded here, and which unquestionably contained a productive mineral zone, is greater than the present producing area of the Leadville district, and hundreds of millions of dollars worth of silver, lead and gold were carried down the Eagle River valley. During the earliest portion of this period, which was prior to the scoring of the Eagle River canyon, the channels and caves on Battle mountain, now so productive, were formed. When the wearing away of the rock on Girard mountain reached the plane of contact the ore was liberated and a small percentage of it was carried by waters, either in suspension or solution, and precipitated in the previously formed cavities in the quartzite. The openings in which the ore is found all contain smooth, polished walls, devoid of angles, and disclose other evidences proving that they are of water formation. The mineral generally consists of an impalpable clay, such as might be found in the bottom of a vessel occupied for some time by muddy water.

The continuance of the quartzite deposits is largely a matter of speculation. So far some of the mines have been opened to a depth along the mineral bearing plane of 600 to 800 feet. The ore channels may continue to produce for

five times this distance, but their character would scarcely warrant this supposition.

The quartzites of New Mexico, carrying silver differ slightly from those of Red Cliff. In the New Mexican quartzites the silver was deposited from percolating waters. The physical conditions of the surrounding country are, however, almost identical. Just above the quartzite ledge is a high, gently sloping mountain, from which this rock has all been eroded down a stream of limestone, which at one time served as the bedding plane for a great ore deposit. With the erosion of this ore body, a portion of its silver contents was taken up in solution, and subsequently deposited in the porous quartzite below, by infiltration. To such an extent was the quartzite impregnated with silver in places that one could stand off at a distance and throw a knife, striking the point firmly in the precious metal.

These two features engender a new field for the search of local deposits of ore in the quartzite. The associations and surroundings of the deposits above described will prove valuable in indicating points at which repetitions may reasonably be looked for. They go to prove that such deposits exist only in quartzites that have formed a barrier or dam across a current from a previously existing ore body. This rule, we believe, will hold good to many other ore deposits in quartzite, besides those so far reported.—*Leadville Herald-Democrat.*

Aluminium.

The Properties of the Metal.

An interesting address has been delivered before the Scranton Board of Trade, Pennsylvania, by the president (Mr. J. A. Price), who, after graphically describing the many valuable attributes of iron and its varied uses, says:

However axiomatic may be everything that can be said of this wonderful metal, it is undoubtedly certain that it must give way to a metal that has still greater proportions and vaster possibilities. Strange and startling as may seem the assertion, yet I believe it nevertheless true that we are approaching the period, if not already standing upon the threshold of the day, when the magical element will be rapidly supplanted, and when this valuable mineral will be as completely superseded as the stone of the aborigines. With all its apparent potency it has evident weaknesses; moisture is everywhere at war with it, gases and temperature destroy its fiber and its life. Continued blows or motion crystallize and rob it of its strength, and acids will destroy it in a night. If it be possible to eliminate all, or even one or more of these qualities of weakness in any metal, still preserving both quantity and quality, that metal will be the metal of the future.

The coming metal, then, to which our reference is made is aluminium, the most abundant metal in the earth's crust. Of all substances oxygen is the most abundant, constituting about one-half; after oxygen comes silicon, constituting about one-fourth, with aluminium third in all the list of substances of the composition. Leaving out of consideration the constituents of the earth's center, whether they be molten or gaseous, more or less dense, as the case may be as we approach it, and confining ourselves to the only practical phase of the subject—the crust, we find that aluminium is beyond question the most abundant and most useful of all metallic substances. It is the metallic base of mica, feldspar, slate and clay." Professor Dana says: "Nearly all the rocks, except limestones and sandstones, are literally ore beds of the metal aluminium." It appears in the gem, assuming a blue in the sapphire, green in the emerald, yellow in the topaz, red in the ruby, brown in the emery, and so on to the white, grey, blue and black of the slates and clays. It has been dubbed "clay metal," and "silver made from clay," also when mixed with any considerable quantity of carbon becoming greyish or bluish black "alum slate." The metal in color is white, and next in luster to silver. It has never been found in a pure state, but is known to

Exist in Combination

With nearly 200 different minerals. Corundum and pure emery are ores that are very rich in aluminium, containing about 54 per cent. The specific gravity is but two and a half times that of water. It is lighter than that of glass, or as light as chalk, being only one-third the weight of iron, and one-fourth the weight of silver. It is malleable as gold, tenacious as iron, and harder than steel, being next the diamond. Thus, it is capable of the widest variety of uses, being soft when ductility, fibrous when tenacity, and crystalline when hardness is required. Its variety of transformations is something wonderful. Meeting iron, or even iron at its best in the form of steel, in the same field it easily vanquishes it at every point. It melts at 1300° F., or at least 600° below the melting point of iron, and neither oxidizes in the atmosphere nor tarnishes in contact with gases. The enumeration of the properties of aluminium is as enchanting as the scenes of a fairy tale. After giving a brief sketch of its birth and development, Mr. Price says: "It was reserved to the distinguished German, Wohler, in 1827, to complete the work of the past 50 years of struggle, and finally produce the minute fine white globule of the pure metal from a mixture of the chloride of aluminium and sodium, and at last the secret is revealed—the first step was taken.

It took 20 years of labor to resolve the mere discovery into the production of this aluminium bead in 1846, and yet with this first step this new wonder remained a fetus undeveloped in the womb of the laboratory for years to come.

Returning again to France some time during the years between 1854 and 1858, and under the patronage of Emperor Napoleon III., we behold Davy as last forcing nature to yield and give up this precious quality as a manufactured product. Rose of Berlin and Gerhard of England, pressing hard upon the heels of the Frenchman, make permanent the new product in the market at £6 8s. per pound. The despair of three-quarters of a century of toilsome pursuit has been broken and the future of the metal has been established.

The Art of Obtaining the Metal

Since the period under consideration has progressed steadily by one process after another, constantly increasing in powers of productivity, and reducing the cost. These are intensely interesting to the student, but must be denied more than a reference at this time. The price of the metal may be said to have come within the reach of the manufacturing arts already. A present glance at the uses and possibilities of this wonderful metal, its application and its varying quality, may not be out of place. Its alloys are very numerous and always satisfactory; with iron producing a comparative rust proof, with copper the beautiful golden bronze, and so on, embracing the entire list of articles of usefulness, as well as works of art, jewelry and scientific instruments.

Its Capacity to Resist Oxidization

Or rust fits it most eminently for all household and cooking utensils, whilst its color transforms the dark-visaged disagreeable array of pots, pans, and kitchen implements into things of comparative beauty. As a metal it surpasses copper, brass and tin in being tasteless and odorless, besides being stronger than either. It has, as we have seen, bulk without weight, and, consequently, may be available in construction of furniture and house fittings, as well as in the multitudinous requirements of architecture. The building art will experience a rapid and radical change when this material enters as a component material, for there will be possibilities such as are now undreamt of in the erection of homes, public buildings, memorial structures, etc., for in this metal we have the strength, durability and the color to give all the variety that genius may dictate. And when we take a still further survey of the vast field that is opening before us, we find in the strength without size a most desirable assistant in all the avenues of locomotion. It is the ideal metal for railway traffic, carriages and wagons. The steamships of the ocean will increase their speed and carrying capacity. A thinner as well as a lighter plate; a smaller as well as a stronger engine; a larger as well as a less hazardous propeller; and a natural condition of resistance to the action of the elements, will make travel by water a forcible rival to the speed attained upon land, and bring all the distant countries in contact with our civilization, to the benefit of all. This metal is destined to annihilate space even beyond the dream of the philosopher or poet.

The Tenelle Strength

Of the material is something equally wonderful. When wire-drawn it reaches as high as 128,000 pounds, and under other conditions reaches nearly, if not quite, 100,000 pounds to the square inch. The requirements of the British and German governments in the best wrought steel guns reach only a standard of 70,000 pounds to the square inch. Bridges may be constructed that shall be lighter than wooden ones, and of greater strength than wrought steel, and entirely free from corrosion. The time is not distant when the modern wonder of the Brooklyn Span will seem a toy.

It may also be noted that

This Metal Affords wide Development

In plumbing material, in piping, and will render possible the almost indefinite extension of the coming feature of communication and exchange—the pneumatic tube. The resistance to corrosion evidently fits this metal for railway sleepers to take the place of the decaying wooden ties. In this metal the sleepers may be made as soft and yielding as lead, while the rail may be harder and tougher than steel, thus at once forming the necessary cushion and the avoidance of jar and noise, at the same time contributing to additional security in virtue of a stronger rail.

In conductivity this metal is only exceeded by copper, having many times that of iron. Thus in telegraphy there are renewed prospects in the supplanting of galvanized iron wire—lightness, strength and durability. When applied to the generation of steam this material will enable us to carry higher pressure at a reduced cost and increased safety, as this will be accomplished by the thinner plate, the greater conductivity of heat and the better fiber.

It is said that some of its alloys are without a rival as antifriction metal, and having hardness and toughness fits it remarkably for bearings and journals. Herein a vast possibility in the mechanic art lies dormant; the size of the machine may be reduced, the speed and power increased, realizing the conception of two things better done than one before. It is one of man's creative acts.

The second oil well at Puente is a success at a depth of 300 feet. A fine body of oil is produced, of rather heavy quality, like that from the other well, but excellent for fuel purposes.

Passing Events.

The demonstration of the Federated Trades took place in this city on Tuesday, the main feature being a torchlight procession in which all the trades unions and mechanics' associations of the city took part. The procession was one of the largest ever seen in San Francisco, and all the proceedings were orderly and quiet.

There seems to be a tendency among mill men at present to look more carefully into the merits of rotary crushers and pulverizers than formerly, when most of them would look at nothing but a stamp mill. Some of the rotary pulverizers have been very successful in our mining regions, and new candidates for public favor are coming forward.

It is reported that many men are going to the Yukon gold fields, Alaska, and also that the Indians object somewhat to the invasion of their ground.

Mining in this State this year promises to be prosperous as many new quartz mines are being opened and old ones are being more rapidly developed.

PLACER mines in the gulches west of Tuscarora, Nev., are penning out well.

Labor in Mines.

A great industry like that of mining is of peculiar benefit to the laboring classes, giving as it does employment to such large numbers of men. The capitalists who go into mining operations, hold a large plant and open up a mine, must perforce employ many men to carry on the undertaking whether it is profitable or not. The capitalist must take his chances on the investment, but the working miner gets his money whether any is made or not, and it is not only those directly employed at the mine and works who are benefited, but twice as many more persons are indirectly gainers by mining work. The wants of the men must be supplied, and other workers supply them, so that every little camp on the coast contributes to the support of more or less people.

It was found in this State, when hydraulic mining was stopped, that it was not only the employees of the companies enjoined who suffered but the community surrounding the mines lost their patrons and felt the depression also. Many were skilled in no other business and were forced to take up new occupations to gain a livelihood.

Even in a camp which is not in "bonanza," or is in a depressed condition, the large amounts of money must be expended for labor in prospecting, etc. As an instance of this may be cited the Comstock region, in Nevada, where the pay-rolls for labor last month footed up as follows:

Con. California and Virginia.....	\$26,532 00
Oould and Curry.....	2,724 00
Hale and Norcross and Savage.....	8,218 00
Mexican.....	633 00
Ophir.....	4,761 00
Sierra Nevada.....	3,870 00
Union Consolidated.....	1,042 00
Union shaft.....	290 00
Belcher.....	2,500 00
Chollar and Combination shaft.....	13,096 00
Crown Point.....	17,807 00
Justice.....	15,161 00
Kentuck.....	3,500 00
Six-mile Canyon pay-rolls.....	9,000 00
Osbiston shaft.....	15,300 00
Yellow Jacket.....	7,207 00
Overman.....	16,423 00
Total.....	4,500 00

\$150,404 00

The pay-rolls of mills engaged in crushing Comstock ore will swell the total sum disbursed to employees during the month of April to \$215,000.

This is only for one month end none of these mines are now paying dividends. Many of them are producing amounts which anywhere else would be considered large, but the product is more than absorbed by the labor and other expenses incurred in the deep mining carried on.

Artesian Well Records.

People are boring artesian wells all over the country, so that the importance of keeping a careful record of the strata encountered in the progress of drilling needs emphasis, both on account of its practical and scientific value. The record should embrace not only accurate measurements of the successive strata traversed, accompanied by careful notes on their character and a full set of samples, but also a full record of all features relating to their water-bearing nature. Some of these that seem trivial often have much significance when critically examined and expertly interpreted. When the diamond drill is used the cores can of course be kept and preserved in their natural order.

The importance of knowing precisely where to locate the permanent packing is apparent. Economy dictates that it should be placed as near the surface as prudent, not only to save the cost of pipe, but also the reduction in the size of the bore caused by the insertion of the pipe, and the consequent increase of friction. At the same time it is important to cut off all dangerous lateral leakage and forestall an early decline in the flow of the well. An accurate knowledge of the strata penetrated is the only trustworthy means of doing this.

Again, when any defect in the first tubing and packing develops itself, a careful record is a valuable aid in detecting the nature and cause of the defect and determining the means for its correction. The original driller may have thought his general observation and memory a sufficient guide for the first adjustment, but if years have passed neither the driller nor his memory may be within available reach. The party contracting for the sinking of a well should invariably insist upon an accurate written record, which should be preserved and transmitted with the property. The authorities of civic corporations superintending

public wells should place such records on file among official documents. Such records are also of scientific value, not only as guides in the antecedent study of proposed wells, but as direct and positive knowledge of the geological column and many subsidiary phenomena.

California Redwood.

The redwood forests of this State are now becoming very valuable, and, notwithstanding this great waste which has gone on for years, there are still immense tracts of these valuable trees. The wood is most excellent for building purposes and has been used for buildings all over the coast. Letely a market has been found for the wood in the East, where it is used for interior decorating a purposes, this color and grain being much admired. We do not see much unpainted redwood in this State, but elsewhere it is highly appreciated. Shelled and varnished it is very beautiful, but oil should never be put on it, as it turns black under such treatment. Bookcases, sideboards and ornamental furniture can be made of it, though such things must be made to order, the manufacturers generally ignoring this wood for such purposes here, on account of its softness.

The California redwood is highly thought of outside of this State. Vessels going to the islands of the Pacific always carry large deck-loads, the planks being as good as gold in the South seas. It is also being shipped to England and there used as a decorative or "fancy wood." When the costly English steam yacht of Sir Thomas Hesketh, the "Lancashire Witch" was in this harbor a few years since, yachtsmen who boarded her were surprised to find her elegant cabins, etc., all furnished in California redwood and "Oregon" pine. It was considered a choice wood and the finish given it by the English workmen made it have a very handsome effect.

The foreign shipments of this wood are now increasing very rapidly. From Humboldt bay alone during the past year they shipped 7,670,000 feet of redwood lumber, as well as quantities of ehingles and moldings, the value of which was \$180,000. These cargoes went to Honolulu, Sydney, Callao, British Columbia, Mexico, Valpareiso, etc.; most of them went to Sydney.

The California redwood trade in 1885 amounted to 113,000,000 feet, and the consumption was 105,200,000. The redwood belt of this State is about 30 miles wide and 400 miles long, running from Monterey bay to Crescent City. It is all on the western slope of the Coast Range. The wood is very durable and is well adapted for ties and posts. For shingles and shakes there is no better wood. It contains little or no resin and burns slowly. The curled redwood, when polished and varnished, is handsome than rosewood. The lumber dealers estimate there is still standing upwards of twenty-six billion feet of this lumber in this State.

THE WABING PULVERATOR, which we recently described in the PRESS, was awarded the highest medal of its class at the exhibition of the Franklin Institute last year. The dry pulverator has recently been in successful operation and is said to give a very perfect product. The dust chamber arrangement and the form of lubrication for the pins of pushing rollers in the dry pulverator are peculiar and we shall shortly describe them in more detail.

W. A. SKIDMORE, for a long time secretary of the Miners' Association of California, and well-known to the mining community of this coast, is very seriously ill at his residence in this city. Mr. Skidmore is the author of a work on mining law, and has been a contributor to the Mint Director's Report for many years, having previously also filled the position of California agent to the U. S. Mining Commissioner.

THOMAS W. DRESSER, a brick-mason and pioneer resident of San Jose, who committed suicide in that city last week while partially insane, was an old inventor. He perfected a number of inventions in the line of quicksilver furnaces, at the time so many quicksilver mines were being worked in this State.

THE Paradise Valley Mining Company employs eighty-seven men.

Manganese.

Manganese ore is known to exist in several localities in this State, and it was formerly mined here to some extent. The deposit on Red Rock, in San Francisco bay, was worked for a while, but within the past three years nothing has been done with any of the California manganese mines. The high rates of freight necessary to market the product have prohibited the development of the mine. This production of manganese in the United States last year was, in tons of 2240 pounds, as follows:

Manganese ores—	No. Tons.	Av. Value per ton.	Total Value.
Virginia.....	18,745	\$9.01	\$168,942
Georgia.....	2,580	5.19	13,390
Arkansas.....	1,453	4.00	5,832
All other States.....	450	4.38	2,017
Total Manganese ores.....	23,268	\$8.18	\$190,281
Manganiferous iron ores—			
Virginia.....	3,237	\$5.35	\$17,318
Total Manganese and Manganiferous iron ores.....	26,505	\$7.33	\$207,599
Argentiferous Manganese ores			
Montana.....	4,263	\$10.00	\$42,630

This table was compiled by Jos. D. Weeks, an agent of the U. S. Geological Survey, who publishes in advance an abstract of this article in Williams' report. In the table under this head of manganese ores, are included those ores that contain the equivalent of 70 per cent of binoxide or 44.25 per cent of metallic manganese. This is the standard of manganese required by the English chemical works. All ores containing less than this are in this report regarded as manganiferous iron ores, though some of them approaching the standard are used in the manufacture of ferro, and all are used for their manganese. The argentiferous manganese ores are only used for their contents of silver, the manganese, however, serving a useful purpose as a flux.

In the following table is an estimate of the production of manganese ores—that is, those ores containing over 44.25 per cent of metallic manganese—in the United States since 1880. This table is to be regarded only as an approximation, though doubtless a very close one:

Production of Manganese Ores in the United States, 1880-1885.

	1880.	1881.	1882.	1883.	1884.	1885.
Virginia.....	3,661	3,295	2,982	5,355	8,950	18,745
Georgia.....	1,800	1,200	1,000	2,580
Arkansas.....	100	175	400	800	1,453	1,453
Other States.....	300	300	375	400	400	450
Total.....	5,761	4,895	4,532	6,155	10,150	23,268

The production of epiegel end ferro manganese in the United States in 1885 was 30,955 long tons, as compared with 30,262 tons in 1884. Assuming 40 per cent manganese as the dividing line between spiegel and ferro-manganese and that all the ferro-manganese made in the United States was made at the Edgar Thomson Steel Works, the production of spiegel in 1885 would be 23,737 tons, and of ferro 7218 tons.

Mining Accidents.

On Monday last Daniel Donahue, a miner working in the Mendenhall chrome mine, near Livermore, Alameda county, was killed by a cave in the mine. These deposits of chrome are opened by small rudely constructed tunnels. The deposits are seldom extensive, and as soon as one is worked out a new tunnel is run for other deposits. Two other miners were slightly injured by the same cave that killed Donahue.

Ward Wells, a carman was killed by a cave in what is known as the blacksmith's tunnel, in the upper levels of the Parker mine, Wood River, last week.

An accident occurred last week in the Lexington mine, at Butte, in which John J. Lynch and David McHyland lost their lives. The unfortunate men went to work in the morning in a cross-cut on the 800 foot level, and they were not seen alive afterward. At 3 P. M., when the shift went to relieve them, both men were found lying dead, and it required but a glance to ascertain that they were killed by an explosion of giant powder. How the explosion occurred must forever remain a mystery, as the two men were isolated when it happened. The most plausible theory, however, is that the men placed a charge of powder which was slow to explode, and that when they returned to examine it the fire reached the powder, the discharge of the blast immediately followed, with such fearful results.

THE Society of California Pioneers have taken formal possession of their new building.

Working Gold-Bearing Sulphurets.

Concentration and Chlorination in Nevada County, Cal.

(Written for Press by C. A. SCHENCK.)

Concentration and subsequent chlorination of gold quartz, carrying, besides free gold, gold-bearing sulphurets and silver ores, which cannot be amalgamated in the battery, is becoming daily of more importance in California, and the financial success of many miners is now and will be only secured by adopting proper means and processes for concentrating the ore and extracting from the concentrates the valuable metals. Considering, therefore, the growth of the quartz-mining industry, which has received of late a new impetus, it may not be amiss if a description of concentration and chlorination, as they are practiced in Nevada county, with especial reference to the Providence mill, is given to the mining public.

The Ore of the Providence Mine

Comes from a fissure, a so-called contact vein, which extends along the dividing line between a belt of slate and a mass of granite, which latter contains, besides its usual constituents, well-developed hornblende crystals, becoming thereby syenitic in character. The solid and lustrous ore-bearing quartz is intersected by seams of chlorite, and contains besides free gold, from five to seven per cent of sulphurets, mainly pyrites with smaller quantities of galena, chalcopryite, arsenopyrite and zincblende. The ore is brought to the mill on a short tramway, where it is dumped into the grizzlies; the fine dirt falls through the bars of the grizzly into an ore bin, while the coarser rock passing over is delivered to two rock-breakers, and falls from these directly into the same bin that holds the fine dirt. Coarse pieces of nearly pure sulphurets, which do not fall through the bars of the grizzlies, are picked out in feeding the rock-breaker and thrown aside for separate treatment. From the ore bin the ore falls through chutes into self-feeders, and is delivered by them to the 40-stamps, divided into eight batteries. From 90 to 100 tons are crushed in 24 hours; water and mercury are fed from the self-feeder side, the latter once every hour, and in changing quantities, as the state of the amalgam on plates may advise; if this is hard, more mercury ought to be charged, and less if it is getting soft. The plates are cleaned every morning, during which time the battery is hung up; amalgam and mercury are (by hand) washed out of the sands obtained in this cleanup; the sands, being not yet exhausted, are then delivered to a grinding pan for further treatment. Through a No. 6 punched screen, which is equivalent in fineness to a 30-mesh sieve, the pulp flows from the battery over the plates, where the amalgam and quicksilver are caught. The amalgam which collects in the battery is cleaned up every four or five weeks, when a sufficient amount has been deposited and repairs make this cleanup convenient.

The First Set of Plates

Which receives the pulp from the battery is of the same width as the mortar by a length of four feet and a fall of $1\frac{1}{2}$ inch to the foot. From there the pulp is delivered to two 16-inch sluices with a grade of 15-16 inch to the foot. They are all covered with silvered copper plates. Immediately after the cleanup of every morning mercury from a small bottle is scattered over the plates, and by means of a rag or a hand-broom uniformly spread out on their surface.

From these sluices the pulp, out of which free gold has been extracted, flows through a launder, with an inclination of seven-eighths of an inch per foot, to the Frue concentrators.

In accordance with one of the first principles in concentration that each particle obtained in the crushing should escape instantly when crushed to the required size, the stamps are run with a high speed (90 to 96 drops per minute) and low discharge, so that but very little slime is formed, and the pulp yet fine enough for an effectual release of the free gold and the subsequent work on the concentrators. The water required in the battery is also regulated with care and with a special regard to concentration, so that just enough water is fed to carry the pulp out of the battery and keep the plates clean from sand, a diluted pulp being not favored at all for the

Work on the Concentrators.

The 16 Frue concentrators are put up in two

parallel rows in a capacious well lighted room, eight in each row and standing head to head. For convenience they are numbered from 1 to 16, all the uneven numbered in one row and the even in the other. One pair of machines receive the pulp from one battery. For instance, No. 1 and 2 from battery 1, by means of a launder overhead, which is connected with the ore spreader by a perpendicular piece of rubber hose $1\frac{1}{2}$ inch in diameter. In front of the little blocks which assist in distributing the pulp uniformly over the ore spreader is an amalgamating plate of corresponding size, to catch the last traces of amalgam and mercury which might escape from the interstices between the blocks. The cleanup of all the ore spreaders after a run from six to nine months is not inconsiderable. The ore spreader is slightly inclined towards the head of the concentrator, to insure a rapid and uniform discharge from its surface, but is perfectly level in a horizontal line which is vertical to the direction of this inclination.

The pulp, deposited on the traveling belt and flowing down towards the lower end, takes also part in the uphill travel and the lateral shaking motion. In this agitated condition, whereby every particle is more or less sus-

Foundry Notes.

There is on exhibition, and in daily operation, at the Pacific Iron Works, on First St., in this city, a Frisbee-Lucop mill for crushing quartz, the first that has been brought to this coast. These mills have been used in the East for some time, pulverizing phosphates, but are well adapted for quartz. Is a centrifugal roller mill of peculiar construction, in which the rollers revolve on their axis and are carried around in a vertical plane on the inner periphery of a heavy ring of hard iron or steel, set vertically inside of a suitable casing, against which they exert a centrifugal force of 1800 to 2000 pounds each, according to their speed.

The Fulton Iron Works are building Tustin's ore pulverizers, which have been very successful lately at the Oro Plata mine, Murphy's, Calaveras county. The mills have been competing with stamps and have shown great efficiency since they have been put at wet crushing.

The Union Iron Works, of Los Angeles, will furnish the iron-work for the new jail of that city.

The frame of a very large building has been put up on the northwest corner of Brannan and

Drift Mining Operations.

We had a conversation this week with Mr. J. B. Sellier, of Placer county, who owns some drift mining property on the Forest Hill "Divide." The rich mines worked near Forest Hill gave to that place such importance that it imparted its name to the entire ridge between the North and Middle forks of the American river, commonly known as the "Forest Hill Divide." There are many old mining hamlets in this section, which has been yielding largely for many years, as along the rivers that bound the divide the mines have been the richest ever found in the State.

Of late this section has been looking up prosperously again, and many mines are being worked on the gravel channel. A French syndicate has possession of a large extent of ground from Indian Springs down, and only this week the engineers left for the divide to locate a tunnel and commence work. The undertaking is to be a very extensive one. The report on the region was made by C. F. Hoffmann and Ross E. Browne, and these gentlemen have gone up to start the work.

In order that the reader may properly understand something about the region in question, we reproduce a small map which we gave about a year ago, with a general sketch of the divide.

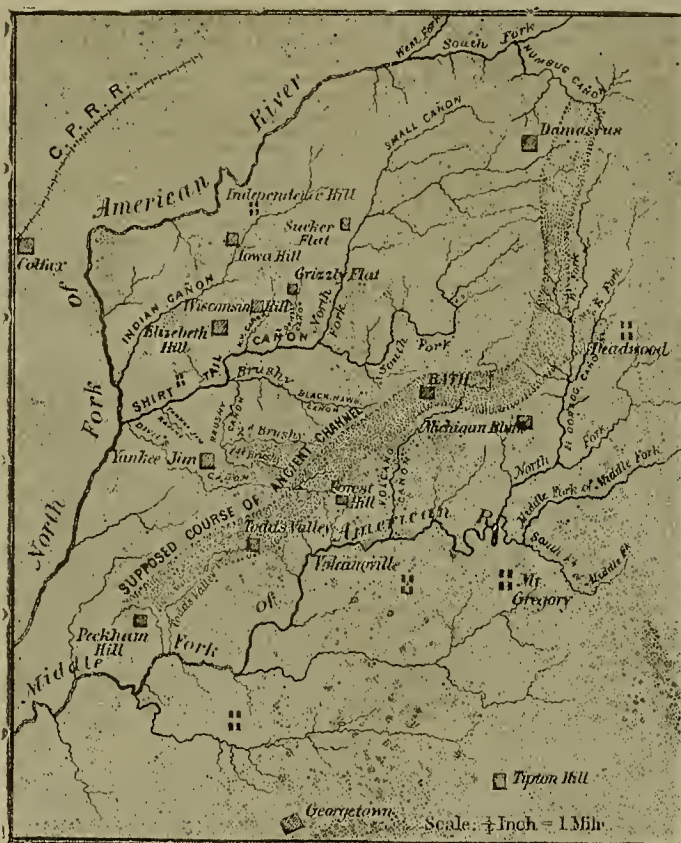

Mr. Sellier informs us of a big strike in the Hazard mine. This mine is not shown on the map, but is on the main channel about $1\frac{1}{2}$ miles from Michigan Bluff. They have a shaft 120 feet deep, and a 3000-foot tunnel from this. The new strike is at the end of the tunnel. They are on the same gravel channel as the well-known Mayflower mine, which has proven so rich. This is the third time the Hazard has been worked. They have run out of means and then stopped, afterwards starting again, but this time they have struck it. The gravel will pay from \$8 to \$10 per carload. The Mayflower is also in rich pay—richer than ever. The mine is in the main channel shown in the map, between the words "Forest Hill" and "Ancient channel," about three miles in a direct line below the Hazard. They crush the gravel from the Mayflower in a mill; the Hazard has no mill yet.

In the Dam claim, which is located about two miles above Sunny South, above the Hidden Treasure, lying east of the old Mountain Gate, Damascus, they have struck gravel worth \$5 per carload recently and are doing well. The Dam claim is not shown on the map but is in the channel represented by the dotted lines, above Damascus and where Humboldt canyon is shown. The claim has been worked a long time and pretty steadily. The tunnel is in a mile. They have no mill, though better results could be obtained by crushing the gravel. They work now by taking out the gravel, washing it, "slacking" the tailings and washing them again. The tailings in some places are left six months or more to "slack."

Mr. Sellier says there is still a big tract of country in this region which has never been worked. He is confident that many river claims will now be opened. The operations of the French company will do much to develop that part of the country and attract attention to it. From Turkey Hill, which is between Deadwood and Michigan Bluff, up to Damascus, the only work done on the channel has been in the character of prospecting. Mr. Sellier says that our map is perfectly correct in showing the course of the ancient channel in which the mines are being worked.

All these mines are worked by drifting, and work can be carried on all the year round. There is no trouble about tailings. In some places the tailings have been worked over three or four times and paid each time. There are many men now prospecting on this channel. From Indian Springs up to Canada Hill there is a big scope of country little prospected. It takes a great deal of money to open these claims, but there is plenty of money in them. A large piece of ground is needed; it will not pay to run a long tunnel to open a small claim. It is for this reason the French company has honed a number of claims which can all be worked by the one tunnel.

The ore bins at the Richmond reduction works are full, and for the present no ore is being shipped down from the company's mine. It is probable that two of the furnaces will be fired up about May 20th.

DRIFT MINING REGION OF THE FOREST HILL DIVIDE.

ended in water and follows the oscillation of the shaking table, the heavier parts have a chance to settle and clinging to the smooth surface of the belt, arrive under the waterspreader, while the light sand is carried down to the foot of the table, where it is dropped into a waste launder.

The separation of the metallic minerals from the larger sized grains of sand, but about the same absolute weight, which were too heavy to be washed off with the lighter sand, is now effected under the jets of water which flow from the waterspreader. The force of the descending water takes hold of these grains of gangue and carries them now also down to the foot of the table; the revolving belt takes with it the particles of metallic minerals which, having weight and less surface and clinging tenaciously to the smooth belt—much more than the sand—offer also more resistance to the impact of the descending jets and are consequently carried over the head of the machine, to be deposited in the concentration box.

(To be continued.)

ABOUT 10,000 mines have been patented in the United States up to January of this year. Mr. Henry N. Copp, of Washington, has recently published a list of them, arranged by States and Territories.

The custom quartz mills of Nevada City are having plenty of work to do.

Fifth streets, and when the building shall have been finished it will be occupied by Garratt & Co. as a brass foundry.

The Pacific Rolling Mills are building a large number of yokes for the new Oakland cable railroad. They are doing all the metal work for the road-bed, and have a great deal of it delivered.

All the men who were at work on the iron mine belonging to the California Iron and Steel Company, at Clipper Gap, have left, the furnace having been shut down.

ADAMANTINE SHOES AND DIES.—Mr. H. D. Morris, of this city, formerly of the firm of Morris and Varney, is introducing a new thing for quartz mills in the shape of "adamantine" shoes, dies and crusher plates. They are warranted to outwear three sets made of any other metal. They are so made as never to break at the shank, and the wear is so light that little or no foreign matter gets mixed with the crushed ore. These appliances are made at the Chrome Steel Works, in New York State, and Mr. Morris has the agency for this coast. The shoes, dies, etc., have stood satisfactory practical tests elsewhere, and are now being introduced here. This chrome steel is also well adapted for drill points and other mining tools.

A LOCAL association has been formed to build a railroad from Billings, Montana, up the Big Horn river 100 miles; capital, \$1,000,000.

MECHANICAL PROGRESS.

A Cheap Mechanical Power.

The distribution of mechanical motive power is receiving increased attention in Europe. Should the problem once be solved, the great factory would disappear, so far as relates as to its repelling feature. The *Paris Temps* has just given an account of a cheap method of distribution which is actually at work in the French capital, in the Rue Beaunour, a locality in which a number of the small industries which peculiarly characterize Paris are carried on. The principle employed is that of rarefied air. By means of a large steam engine a vacuum of 75 per cent is produced in a pipe, from which smaller tubes branch off to each workshop. The workshops are severally provided with small motors, worked, of course, by means of the difference of pressure between the density of air in the tube and that of the atmosphere. Thus, the power can be distributed in quantities no greater than may be needed to work a sewing machine, for instance. Each workman is supplied with an automatic registering apparatus, and as he is able to shut off the power when it is not required; he is charged only for the quantity actually used. A fixed monthly rent is charged in addition to the installation, the rent being proportionate to the size of the motor in the workman's room. The principle of rarefied air has been adopted in preference to that of compressed air, because there is less danger of accident, and the inconveniences which might arise from the chilling consequences of the use of compressed air in small workshops are avoided. The importance of the economic distribution of motive power in fractional quantities in Paris is indicated by the fact that in one municipal division alone there are 5000 persons engaged in small industries, who require in the aggregate from 1000 to 1200-horse power per day. Taking the entire population of Paris, 40 per cent are engaged in such small industries.

RUSSIAN SHEET IRON.—The following method of manufacturing Russian sheet iron is given in "Calvert's Almanac." Selected iron is hammered into slabs of the right size, and to make a finished sheet the slab is passed through rolls, making 75 to 80 revolutions, three or four times, after which it is hammered again. Several sheets were then heated to a full red heat, covered with charcoal shaken on to them from a bag made of coarse linen, and are then piled with covering sheets of heavier iron top and bottom. The pile is then worked down under a heavy hammer until nearly of the finished size. When cool the hammering ceases, the plates are separated, reheated, and piled again with cold plates interposed, the hot and cold sheets alternating in the pile. This hammering is then repeated until they are cool, after which they are cut to size.

THE SUPERHEATED WATER THEORY.—The report of a committee appointed by the French Academy to inquire into the superheated water theory of steam boiler explosions has been published in the *Annales des Mines*. The committee did their work very thoroughly. They constructed suitable apparatus, experimented in the most exhaustive manner with it, and investigated several explosions claimed by the advocates of the theory to have been due to this cause. They failed utterly to superheat water under all conditions which could possibly occur in practice, and all the explosions investigated were shown exclusively to have resulted from simple deterioration of the boilers, or from carelessness. Their refutation of the theory is most signal and complete.

INSIDE SAFETY CHECK VALVES.—Many lives have been sacrificed by the breaking of steam or feed pipes connecting with boilers. This danger is said to be wholly overcome by a recently devised inside safety check valve, invented by the superintendent of motive power of the Pennsylvania Railroad Company. The valve, being located inside the boiler, is absolutely protected in case of collision and is certain to prevent such serious loss of life as has occurred where the feed or steam pipe connections have broken off from this or other causes. This valve, it is said, can be used on locomotive, stationary and marine boilers with equally good results.

SOMETHING NEW IN BOILERS.—A boiler has been made in France, in which the metallic surface exposed to fire, does not touch the water. The boiler, it is said cannot become red hot, but is enveloped all over by the same temperature. The vaporization is very great, and the last drop of water can be converted into steam, without any danger of explosion.

IN CHIPPING IRON.—To chip smooth after the chip has been started, the chisel should always be held at the same angle at which the chip was started and every blow of the hammer should be as near alike as possible; then, with common sense and practice, a person can chip nearly as smooth as he can file.

IN TUBULAR BOILERS the hand holes should be often opened and all collections removed from over the fire. When boilers are fed in front and are blown off through the same pipe, the collection of mud and sediment in the rear end should be often removed.

English or German Steel Castings.

Quite an animated debate occurred at a recent session of the Newcastle-on-Tynes Association of Foremen Engineers on the relative merits of English and German steel castings. Mr. Surtees, the chairman, alluded to the statement of a well-known man who had said that he bought steel castings from Germany, not because he got them free of duty, but because they were better than the home production. Another member, however, showed that as far as the cost was concerned there was a very material difference in favor of England.

Regarding the quality of the German castings, one member said that there was a firm in Germany who could turn out articles of a better appearance and surface than they could in England, but so far as the quality, generally, was concerned the German productions were greatly inferior to any English. "Even the superior looking steel from Germany was not nearly so good as that of England." The better surface of that special German steel might possibly be produced by some annealing process used by that one firm alone, but otherwise the whole texture and strength of the steel was far from being so good as the English material.

Will German Castings Stand the Test?

Several members stated it as their experience that German castings would not stand the requisite test, and "inspectors were known who were disgusted with it and would not pass it." The meeting generally agreed that the continental metal was lacking in solidity and toughness, but no definite opinion was expressed in the absence of scientific tests. The debate finally ran into the question of "protection," one member asserting that the only way to protect themselves from German steel was to put a duty on it. A Sheffield man recently said, on another occasion, that "the workmen of Sheffield will have less work to do if we do not close our ports against German goods." The question of protection appears to be rapidly growing in favor among many of the tradesmen and manufacturers of England.

COILED WIRE BELTING.—This comparatively new description of belting appears to be giving very good satisfaction wherever it has been introduced. It is used only for comparative light work, and of course requires good pulleys, such as are used for ropes. The belt is simply a coiled wire with its two ends simply hooked together. It is made of tempered steel wire and also of brass wire for light work, and is claimed to be ten times more durable than ordinary belting. The belt runs without slipping and which is quite peculiar, it continually changes its position, rotating at right angles to its forward motion while passing round the pulley. The surfaces of the coil thus wear uniformly. The ends of the belt may be simply hooked or fastened together by screwing hook-and-eye connections into the ends of the coil, or by swivel connections. By using friction clutches the belts can be used in the places of belts that are shifted at will from fast to loose pulleys. They can also be employed as straight, quarter, twist, cross or corner belts at any length, and for all purposes where leather or other belting is now used. Increase of power is also claimed as a result of using these belts.

THE WEARING OF BOXES.—One very frequent cause of boxes running hot is that by wear or grit or other causes the bearing will have grooves running around its circumference. In this case it is difficult for the oil to pass by these grooves and projections, and although one end or the middle of the bearing gets oil, the other is left without it. In this case, it is a good plan to file the bearing in the direction of the length of the shaft, but never in the direction of the shaft run—that is, following its circumference. This will give relief to bearing when almost everything else has failed. To avoid accidents from this cause high grade oils should be used, with self-oiling bearings. The shafting should be kept true and in line. All accumulations of dust, dirt, flyings, etc., should be frequently removed from bearings to prevent undue friction, as the heat thus generated may remain latent for some hours after the machinery has ceased running, and burst into flames when least expected, hence all important bearings should be frequently inspected during the first three hours after shutting down, in order to prevent disaster from this cause.

AN IMPROVED RAILWAY SEAT SPRING.—There is now on exhibition at the Royal Aquarium, Westminster, a new form of seat spring, which is applied, among other things, to the seats of railway carriages. The entire seat is carried on a coiled steel spring of peculiar form and is most luxurious, being free to move in all directions, so that every jerk and oscillation which the carriage can receive, is perfectly taken up. The springs are made by Mr. John Harrington, of Coventry.

THE PRESSURE GAUGE being an important fitting on a boiler should be so made that the figures on the dial can be easily read across the boiler room, so placed that it can be seen without hunting for it, and so put up that it shall at all times be subjected to the steam pressure in the boiler, and no other pressure, and should be corrected and kept correct by comparing it as often as may be convenient or necessary with some standard known to be correct.

SCIENTIFIC PROGRESS.

Manufacture of Crystal Balls.

Most of our readers have no doubt seen samples of those beautiful little spheres of rock crystal (quartz), which when very small are sometimes attached to watch chains; but, often, of larger size cherished and shown as mechanical curiosities. It has heretofore been supposed that they could only be manufactured by Japanese, from which country they have been introduced. It has been thought that no other people had the skill and patience to fashion such a hard substance as quartz crystal into such beautiful and perfect spheres.

For this reason such crystals, especially when of large size, such as from four to seven inches in diameter have been disposed of at fabulous prices. One of four and a half sold as high as \$1725; another of seven inches is held at a valuation of \$5000. It is the mystery which surrounds the production of these gems of art which has given them such value. It has been claimed that they are much harder than ordinary quartz crystals; but it is well known that such crystals are always and everywhere of precisely the same hardness. Those of sufficient size, however, to admit of being worked into spheres of the largest diameter are somewhat scarce. But still such are often found in the neighborhood of the gold mines of North Carolina, and some very large ones, we believe have been found in California.

A correspondent of the *Scientific American*, Mr. Wm. H. Hadden, of Newark, N. J., recently made a successful effort to have them manufactured in this country, the result of which is given substantially as follows: "I enlisted the services of a skilled lapidary, putting into his hands a piece of clear material from North Carolina, suitable for cutting a small sphere, and urging him to lose no time in completing the work. I was somewhat surprised and pleased to receive from the lapidary the finished ball within a week from the time the rough mass was put into his hands, the ball being perfect in every particular of roundness, polish and pellucidity. It measured two inches in diameter, and possessed every perfection and attraction belonging to a Japanese crystal ball."

This perfect sphere of quartz, the largest ever cut in America at the time, was exhibited at the North Carolina State Exposition of 1884 and at the New Orleans Industrial Exposition of 1884-85, at which places it received many encomiums from the press, as evidencing the resources of our country and the skill of American labor.

This article is particularly called forth by the completion, on Apr. 3d of this year, after only ten days' labor, of a superb crystal sphere measuring three and one sixteenth inches in diameter, and weighing exactly one and one-half pounds. As a piece of American workmanship in crystal, it stands alone, at this time; and in its various perfections is unexcelled, excepting in size, by any similar Japanese effort that has come under the writer's notice.

Therefore, possessing the requisite material, we can henceforth make crystal spheres, lenses, or even "bottles of stone," here within the United States, if the dilettanti should require them, or fashion demand such articles of luxury.

FORCE IN PLANT GROWTH.—The force exerted by growing plants can be easily measured. Darwin took a spring clothespin, measured the force necessary to open it, and then fastened it upon the growing root. He found that the pressure was of many ounces. President Clarke of Amherst Agricultural college made some interesting experiments with a growing squash, which was harnessed and had levers attached in such a way that the force exerted could be ascertained. It was equal to thousands of pounds, and finally the harness broke. In a graveyard at Hanover, Germany, a block of stone containing twenty cubic feet has been thrown out of place by a tree growing from a seed which germinated in the crevice of the rock. It has already been lifted over five inches.

HEARING.—It has been found by Dr. Tait that the ear in women can perceive higher notes—that is, sounds with a greater number of vibrations per second—than the ear in men. The highest limit of human hearing is somewhere between 41,000 and 42,000 vibrations per second. Few persons have equal sensibility to acute sounds in both ears, the right ear usually hearing a higher note than the left. The lowest continuous sounds have about 16 vibrations per second.

THE AVERAGE HEIGHT OF EUROPE has been estimated by a German geographer to be 974 feet. Switzerland shows the greatest mean height, 4624 feet, and the Netherlands the least, 31 feet. Intermediate are Spain and Portugal, 2298 feet; Austria, 1695; Italy, 1696; France, 1292; British Islands, 714; Germany, 701; Russia, 548; Denmark, 115.

TELESCOPES.—The principle of telescopes was described by Roger Bacon about 1250, and Leonard Digges, who died about 1573, is said to have arranged glasses so that he could see very distant objects. Galileo constructed telescopes in 1609, and discovered Jupiter's satellites in 1610.

A New Saccharine Substance.

Allusion has already been made in these columns to a new saccharine substance which has recently been obtained from coal tar. It has heretofore been known as "benzoyl sulphuric imide," but it will hereafter be known by the simpler term—"saccharine." The discoverer is Dr. Fahlberg, and its preparation and properties were recently described by Mr. Ivan Lsvinstein at a meeting of the Manchester Section of the Society of Chemical Industry. Saccharine presents the appearance of a white powder, and crystallizes from its aqueous solution in thick, short prisms, which are with difficulty soluble in cold water, but more easily in warm. Alcohol, ether, glucose, glycerol, etc., are good solvents of saccharine. It melts at 200° C., with partial decomposition. Its taste in diluted solutions is intensely sweet; so much so that one part will give a very sweet taste to 10,000 parts of water. Saccharine forms salts, all of which possess a powerful saccharine taste. It is endowed with moderately strong antiseptic properties, and is not decomposed in the human system, but eliminated from the body without undergoing any change.

It is about 230 times sweeter than the best cane or beet-root sugar. The use of saccharine will therefore be not merely as a probable substitute for sugar, but it may even be applied to medicinal purposes where sugar is not permissible. One part of saccharine added to 1000 parts of glucose forms a mixture quite as sweet as ordinary cane sugar. The present price is 50 s. per pound, but although very high, this is not prohibitory, as its sweetening power is so great; but it is probable the cost of its manufacture will soon be very considerably reduced. The *Brewers' Guardian* says: "This new compound will be of great interest to brewers, for not only is it perfectly wholesome, but it possesses, in addition to its intensely sweet taste, decided antiseptic properties, and therefore may be usefully and advantageously added to beer."

Interesting Results of Deep Sea Explorations.

Among the interesting results of submarine or deep-sea explorations conducted under the auspices of the London Geographical Society are those in reference to the Atlantic sea bed. It would seem that the bottom of the North Atlantic is occupied by two valleys, the eastern extending from 10 to 30 degrees west longitude, and traceable as far as the equator, with an extreme depth of less than 13,000 feet, while the western valley reaches from the 30th to the 50th degree of west longitude. The two are separated by a ridge in 30 degrees west longitude, along which the average depth is only 1000 fathoms, and which can be traced northward to Iceland and southward to the Azores; it is volcanic in character at both extremities. Its extreme breadth is somewhat less than 500 miles, and the depth of the water increases on both sides of it according to the distances of the axis.

A Volcanic Region in the Atlantic.

Another interesting discovery has recently been made known which is alluded to as follows: Recent observations indicate the existence of a submarine volcanic crater between the Canary islands and the coast of Portugal. From a cable-laying steamer, in latitude 39 degrees 25 minutes north, longitude 9 degrees 54 minutes west, the water was found to measure 1300 fathoms under the bow and 800 fathoms under the stern, showing the ship to be over the edge of a deep depression in the ocean bottom. An English geologist, T. Mellard Reade, remarks that great inequalities are found in the bed of the sea of Lisbon, due probably to a submarine chain of mountains.

TORNADO POINTS LOCATED.—In a report to the French Academy of Sciences, on the 172 tornados recorded in the United States in 1884, Mons. Faye considers it established that there is a definite portion of an era of low barometer most favorable to tornados. The signal service reporters are now endeavoring to determine this "dangerous octant" still more accurately. A memorable day in the history of tornados was Feb. 19, 1884, when no less than 45 was recorded in the southeastern States, attended with a total loss of 800 lives, and 2500 injured, 10,000 houses and buildings destroyed, and 15,000 people left homeless.

PHOTOGRAPHIC PROGRESS.—The possibility of photographing in the dark has been shown by Abney, an English experimenter. He has succeeded in preparing plates which are sensitive to the rays lying beyond the red end of the spectrum—the dark heat rays—and with such plates used with a rock salt lens it should be possible to photograph bodies having a high temperature, although that temperature may be far below that necessary to render them self-luminous.

NORTH AMERICAN FISHES.—Naturalists now count no less than 1870 different kinds of fishes in North American waters, of which 590 live in the rivers and lakes, and 550 kinds belong to the Pacific. Of the remainder, 105 dwell only in the deep waters of the Atlantic and Gulf of Mexico, never approaching the shores or the surface.

ENGINEERING NOTES.

Railroad Activity in California.

Great activity in railroad building is manifested just now in this State. It has long been felt that there are many undeveloped localities and some extensive regions in the State which need short lines of railroads to connect them with the great main arteries of commerce which traverse the State along its principal lines of travel. The time has come when no community can expect much prosperity or any considerable growth without the modern facilities of transportation. Our principal railroad builders have evidently become impressed with the idea that the people are so earnest in their demands for these improvements, and that if they do not provide the facilities needed others will. Under this stimulus the Southern Pacific is extending its line from Soledad down through Santa Barbara and San Luis Obispo counties, a rich region heretofore fenced in by mountains. The California & Oregon is being rapidly pushed to completion and so is the California & Nevada. The San Francisco & North Pacific is about to build a cross-country branch running to Napa Junction. A narrow gauge road is projected in Lake county. The South Pacific Coast is building a branch running to New Almaden and is projecting other work. The North Pacific Coast talks of an extension toward the north along the coast. The Southern Pacific Company intends to speedily build a branch which will run up into Mendocino county and tap the rich lumber region. A number of small narrow gauge roads are either being built or are projected in various parts of the State. This is all very satisfactory and augurs well for the progress of the State. A contemporary truly says: "We need these roads badly, and the more we get of them the better, for by their aid the faster the State will grow and the richer will it get."

ANOTHER GREAT BRIDGE.—Some \$3,000,000 are to be expended in a giant bridge across the Ohio river at Cairo, Illinois. The structure is to be built by the Illinois Central Railroad Company, and will require more than three years for its completion. The bridge will be entirely of steel, and will rest on piers of solid masonry about 170 feet high or more, and a truss pattern, extra heavy, will probably be chosen. The question of fixed span or draw has not been determined. The length of the bridge will be about 5000 feet, and there will be an equal length of iron or steel approaches ascending at a grade of about 40 feet to the mile to the level of the bridge. But a single track will be provided for. The low bottoms on both sides of the river render the undertaking one of great magnitude, but its importance would seem to overshadow the difficulties to be overcome. Such a plan has been proposed from time to time in the past, but never came to a focus. The present one is a result of increasing urgency, and no obstacles dangerous to its consummation have presented themselves.

HYDRAULIC POWER DISTRIBUTION on a large scale is still gaining favor in England, and since the first attempts in that line made in Hull about eight years ago progress has been steady and encouraging. The London Hydraulic Power Co., which is now attracting special attention, was organized in 1882 by the originator of the Hull scheme, and in both cities financial success has been thoroughly assured. The consumption of water has rapidly increased since operations were commenced, and the power is now extensively employed at docks and railway stations, in warehouses and manufacturing establishments, and for operating elevators, cranes, presses, hammers, etc. Thus far there have been remarkably few leaks or breaks, which is especially remarkable when it is remembered that these pipes must be threaded through the intricate system of other pipes, conduits and tunnels already existing in underground London. Liverpool is to have a similar system for the supply of water power.

AN IMMENSE DYNAMO.—The Brush Electric Company, of Cleveland, are building the largest dynamo in the world. It will be 12 or 13 feet long, 5½ feet wide, and weigh ten tons. It will give a current of 122,500 amperes; a number of watts, 245,000. In the world it will be four times the size and capacity of the "Jumbo" machine exhibited by Edison at the Electrical Exposition at Philadelphia. The latter was adequate to the task of running 5000 sixteen candle power incandescent lights. This monster machine of the Brush people will be shipped to Lockport, N. Y., and used for the smelting of "aluminum," it is said. Five hundred horse-power will be required to drive it, which will be furnished by water, with the aid of turbine wheels.

THE SONOMA INDEX TRIBUNE says that a corps of engineers is actively engaged in surveying the proposed branch road from Novato to Sears' Point, on the line of the Sonoma Valley Railroad. It appears that an extension to connect with the Central Pacific is not contemplated.

TELEGRAPHIC FACILITIES are being rapidly extended so as to connect all the great commercial centers. Peking, the capital of China, is now connected with London by telegraph.

USEFUL INFORMATION.

How to Design a Monogram.

Scarcely anything seems so easy as to design a monogram, yet we see very few successful ones, the most of them being a mass of mixed up letters and ornaments of which we can find neither the beginning nor the end. There is a law regulating the designing of everything, and it is this law which the true designer keeps in mind and applies to his work; the effects of obedience to this law and its violation are seen as clearly in the design for a monogram as in the design for a cathedral.

First, there should be harmony of composition, that is, the letters should so emphasize, subdue or control each other that the composition should impress us as compact, appropriate and, being so, beautiful.

Second, there should be an unnecessary ornamentation; there should be a quiet and peace about the design which will always please the truly artistic. Looking at some designs, we get the impression that ornament was so plentiful that the designer saw no other means of consumption than that of hurrying his designs in it, for we see that there is a mass of curves, angles, shades and leaves, but nothing else.

Third, simplicity of lettering is an important requisite, as there should be no possibility of mistaking an E for a G or C, and the boundaries or outlines of the letters should be well defined.

Fourth, the order of sequence of the letters should be carefully attended to.

The common idea is that a certain number of letters are given with which to make a pleasing design, and so far that impression is right; but there is something beyond this. There is the art of so placing the letters that one can distinguish at a glance the first, the central and the last letter. Now, the rule to be observed to secure this result is as follows: The last letter of the monogram must be the principal feature and must be the largest, the boldest and the heaviest letter; then the first letter must be the next in size, but the lightest in outline and color; then the central letter must be the smallest, and of an intermediate tint. If the monogram is of four letters, the two intermediate must be of the same size, and the second letter lighter in outline and color than the third.—*Art Amateur.*

COST OF CARS.—A first class standard eight-wheel American locomotive, with automatic train and driver brakes, is worth \$7000. A modern sleeper, with 42-inch steel-tired wheels, six-wheel trucks and steel axles, is worth about \$10,000. A parlor car, with 42-inch steel-tired wheels and steel axles, toilet room and upholstered chairs, is worth about \$5800. A first class coach, with toilet room, patent car warmer, 42-inch steel-tired wheels and steel axles, is worth about \$5500. A second-class coach, with 33-inch steel-tired wheels and steel axles, and patent car warmer, is worth about \$4200. A postal car of modern design, with 42-inch steel-tired wheels and axles, is worth about \$3000. A 50-foot baggage car, of modern design, with same running gear, is worth about \$2000. A standard 34-foot box and stock car, with swing motion trucks and cast wheels and iron axles, is worth about \$400. A coal cart with same trucks is worth about \$325. A standard flat car is worth about \$300. Caboosees are worth from \$800 to \$1000, owing to the build.

STEAM VS. HOT AIR FOR CASKS.—We suppose that no difference of opinion exists at the present time respecting the evil of steaming casks. Not only do you cause the timber to perish, but you provide in the most efficient manner, for the early acidity of the wood surface if left exposed to atmospheric influence. Now, hot air, in motion, at a temperature of 350 degrees F., has quite a different action. Long practice has demonstrated that such a temperature of traveling air has no influence on the wood itself, while it is sufficient to kill all germs of whatever type, and all traces of evil smell or mouldiness will be removed. We cannot commend the system too highly, being convinced that it is far superior to any other method of procuring not only clean but dry and sweet shipment casks; for few are aware, perhaps, of the evil effects of using casks for racking which, for instance, are not free from excessive quantity of moisture.—*Brewers' Gazette.*

MUSICAL SEWING MACHINES.—The latest attachment to the sewing machine is a mechanical device by which the machine, when in motion, plays a succession of lively tunes. Another mechanical novelty interesting to ladies is the application of electric light to piano-fortes. The material and mechanism are concealed inside the case, so that the light is provided for the performer without any apparent disturbance of the ordinary arrangements. Both these inventions are of French origin.

TO REMOVE CLINKERS.—To remove clinkers from the stove, sprinkle common table salt on the linings when the stove is cold. Use plenty of it. Build a moderate fire—wood and coal—and in a day or two the clinkers will be gone.

CAYENNE PEPPER blown into the cracks where ants congregate will drive them away. The same remedy is also good for mice.

MAPLE SUGAR.—Wiley has examined the sap of the sugar maple, and finds that saccharose is almost the only sugar present; it varies from 1.95—3.5 per cent. Maple sugar generally contains more than 80 per cent of saccharose. The sap contains .0088—.0103 per cent albumoids; no starch; acid equal to .00005—.005 per cent malic acid; and ash .146 per cent. A very little glucose is found toward the end of the season. This peculiarity of maple sugar renders its adulteration very easy. A Painesville, Ohio, paper says that a farmer recently brought to town and sold 500 pounds of what he called new sugar. A day or two after a Painesville gentleman visited the "bush" of said farmer and found not a tree had been tapped this year. The farmer informed the gentleman, however, that a good way to make new sugar early was to "mix last year's sugar with canned syrup, boiling together gently."

TO DETERMINE THE SIZE OF A BLOWER.—A correspondent of a lumber journal asks: "How can I determine the size of a blower necessary to remove sawdust and shavings from a flooring machine, a large angle surface planer, a four side 'sticker' and a small circular saw?" The answer is given as follows: The pipes from the above machines should be respectively 7, 5, 4 and 3 inches in diameter. Circles are to each other as the squares of their diameters; therefore, the area of the four pipe is about equal to one pipe 10 inches in diameter. A blower should be in diameter, about three times that of its induction pipe, which in this case will make it 30 inches. We should by all means put in a 36-inch blower which will allow you to put in an extra pipe or two in case you enlarge your plant.

A MURAL MIXTURE.—Pulverized steatite is coming into use as a very superior finish for walls and ceilings. Steatite is simply soapstone. When put upon the wall it takes a high polish, is pearl gray in tint and presents the best possible surface for painting, whether in oil or water color, and will neither crack nor chip. It can be washed without injury, and when subjected to heat, moisture or chemical fumes it gives no smell and does not turn yellow with age. It appears to be well adapted for hospitals, factories, cellars, markets, etc.

INCREASE IN THE CONSUMPTION OF SUGAR.—As late as the year 1700, all England consumed only 20,000,000 pounds of sugar in the course of the year, but since then the consumption has greatly increased, twenty million hundred weight now being used by the English people. The process of refining sugar was not known previous to 1659. The increase in sugar in this country, has been much greater in proportion than in England.

GOOD HEALTH.

INFLUENCE OF TOBACCO ON THE HUMAN SYSTEM.—One of the effects of tobacco is a tendency to produce fatty degeneration of the tissues, nearly all of them being subject to this. The popular notion that the use of tobacco will prevent corpulency is a deception, except as it interferes with healthy nutrition. A very general effect is fatty degeneration of the muscles, especially those of the heart. Persons whose systems are saturated with tobacco are very slow in recovering from sprains or bruises of the muscles, nor do they bear surgical operations well. But the most serious effect is "tobacco heart," which is a rupture of this organ from the deposit of fat cells in the fibers of the muscles, which destroys their integrity and is immediately fatal. It occurs mostly in young persons. Another effect of tobacco is a tendency to produce cancerous affections. Fat is the lowest healthy tissue; its uses are to store up the means of nourishment. A little lower than this we find cancer cells in the blood and in various tissues. Tobacco changes the condition of the blood, reducing the disks, which in the healthy condition are round like a coin and regular, to about two-thirds their natural size, and making them rough and wrinkled.—*Henry T. Child, M. D.*

EXPERIMENTAL YELLOW FEVER.—Dr. Carlos Finlay, of Havana, has published the results of several experiments he has made on the inoculability of yellow fever. He performed the operation, or rather got it performed for him by mosquitoes, which he caused first to sting a patient suffering from yellow fever and shortly afterward a healthy person who was to be (with his own consent of course) the subject of the experiment. He found that the disease was only inoculable from the third to the sixth day. When two mosquitoes were employed, so that a double dose was given, the symptoms of the experimental disease were somewhat more severe than when only a single mosquito was used. Of eleven cases of inoculation, six were efficacious, one doubtful and four negative. The period of incubation varied from five to 14 days; the symptoms consisted of headache, pyrexia, injection, with sometimes an icteric tint of the conjunctiva, and in some cases albuminuria. The fever lasted, as in the ordinary form, from five to 21 days. The author believes that this method of producing artificial yellow fever will ultimately be found very valuable as a prophylactic against the natural and dangerous form of the disease.—*Lancet.*

Curative Power of Water.

There is no remedy for such general application and none so easily obtainable as water, and yet nine persons in ten will pass it by in an emergency to seek for something of less efficacy. There are but few cases of illness where water should not be given the highest place as a remedial agent.

A strip of flannel or a napkin folded lengthwise and wrung out of hot water and applied around the neck of a child that has the croup will usually bring relief in ten minutes. A towel folded several times and quickly wrung out of hot water and applied over the seat of pain in toothache or neuralgia will generally afford prompt relief. This treatment in colic works like magic.

We have known cases that have resisted treatment for hours yield to this in ten minutes. There is nothing that will so promptly cut short a congestion of the lungs, sore throat or rheumatism as hot water when applied promptly and thoroughly. Pieces of cotton batting dipped in hot water and kept applied to all sores and new cuts, bruises and sprains is the treatment now adopted in hospitals.

A sprained ankle has been cured in an hour by showering it with hot water poured from a height of three feet. Tepid water acts as promptly as an emetic, and hot water taken freely half an hour before bedtime is the best of cathartics in the case of constipation, while it has a most soothing effect on the stomach and bowels. This treatment continued for a few months, with proper attention to diet, will alleviate any case of dyspepsia.—*Ex.*

DISEASE AND DUST.—Within the last few years some attention has been given to the diseases which are directly traceable to the inhalation of air charged with particles of dust. It is well that preventive measures should be taken in order to insure protection to workmen against the injurious effects of dust. The air in workshops should be renewed three times an hour. The introduction of fresh air and the expulsion of the air in the room will very materially lessen the dust, and save the lungs. Better, however, than this, are contrivances for drawing off the dust immediately from the place where it is produced. Where there is but a little, the airing produced by chimneys may be sufficient; where there is a great amount it should be drawn off by a revolving apparatus creating a continual current of air.

VACCINATION FOR CONSUMPTION.—The chief disease of temperate climates being consumption, any means which will check its ravages must be hailed with joy and gratitude by a large part of the human race. In France is now projected an experimental inquiry into the possibility of finding some method of attenuating the supposed virus of consumption so as to make inoculation therewith practically useful against the disease, either as a preventive measure, like vaccination against smallpox, or as a means of cure, like Pasteur's inoculations in hydrophobia. Although the chances of success are remote, the investigation is approved by eminent scientific men and a considerable sum has been subscribed toward defraying the expenses.

MALARIA ALTITUDES.—While malaria has its ordinary habitat in low-lying regions, it may, under favorable conditions, exist at great elevations. On the Tuscan Apennines it is found at a height of 1100 feet above the sea; on the Pyrenees and Mexican Cordilleras, 5000 feet; on the Himalayas, 6400 feet; on the island of Ceylon, 6500 feet, and on the Andes, 11,000 feet. At present, the elevation of entire acuity has been thus approximated for various places: In Italy, 400 to 500 feet; in California, 1000 feet; along the Appalachian chain of the United States, 300 feet; in the West Indies, 1400 to 1800 feet. In any of these regions, however, malaria may drift up ravines to an indefinite height.

DISINFECTING OF ROOMS.—M. Koenig recommends mercuric chloride. The windows, chimney, etc., are carefully closed up, and 50 grams mercuric chloride are placed in any suitable vessel, which is then set on a pan of burning charcoal, the operator immediately leaving the room and closing the door. After about four hours he re-enters, with a cloth over his mouth and nose, and throws open the windows. After some hours of ventilation a slight atoning with sulphur is made to follow, which neutralizes any remnant of mercury. This process not merely disinfects, but destroys all kinds of vermin.

BLEEDING AT THE NOSE.—The best remedy for bleeding at the nose, as given by Dr. Gleason at one of his lectures, is in the vigorous motion of the jaws as if in the act of chewing. In the case of a child a wad of paper should be inserted to chew it hard. It is the motion of the jaws that stops the flow of blood. This remedy is so simple that many will feel inclined to laugh at it, but it has never been known to fail in a single instance, even in the severest cases. So says the *Scientific American*.

TEA.—Dr. Burney Yeo, of London, reports the curious observation that there are persons who usually drink tea without injury, but in whom when in a depressed mental condition it occasions indigestion and palpitation of the heart.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

Downs.—*Ledger*, May 8: We learn that work on the Downs mine near Volcano is to be resumed forthwith. At a meeting of stockholders held recently it was decided to spend \$15,000 in prospecting. The shaft is to be sunk deeper. No shaft of 600 or 700 feet has been sunk in the entire district, and hence the idea prevails that the gold-bearing quartz exists only near the surface. But the truth or falsity of this proposition has never been demonstrated, but an effort in that direction is now about to be made by this company. George W. Parker is to superintend the operations.

AMADOR CITY NOTES.—A correspondent sends the following mining notes: The Gover mine is running its 20-stamp mill on good rock at present, having struck a large body of the same a short distance north of the old shaft. The friends of Mr. Call will, undoubtedly, be pleased to hear this good news, as he has had uphill work at this mine ever since he started two years ago. The Bunker Hill appears to be starting on a new era of prosperity. The mine has been looking very poor for some time, so much so that only a portion of their 40-stamp mill has been running. Recently they have struck a body of ore on the 700-foot level that prospects quite well. They are now running 20 stamps on this ore, and if it proves as good as it looks more stamps will be running very soon. The company is taking advantage of this partial stoppage of the mill to make a thorough overhauling of their Frue machines, and with new belts will make the machines as good as new. Their chlorination works are still in operation, having been run continuously for 12 months on sulphurets made by their own mill. The old Keystone keeps on as usual, and well merits the term applied to it by the San Francisco people, viz., Old Reliable. The South Spring Hill people continue to talk about the wonderful offers they have had for their property, ranging from \$1,000,000 to \$2,000,000. If it is half as good as they represent it Amador can well be called the banner town for good mines. The Wabash, just south of the South Spring Hill, is rapidly coming into prominence. Although but little prospected it has a good reputation outside. About 200 tons of ore was taken out last season and crushed at the Mahoney mill in Sutter creek. The results of this test proved to the owners they had a good property. The principal owner, L. T. Lewis, secretary of the Keystone Company, thinks there are "millions in it," and he will not be likely to sell this mine unless he gets a handsome price. On the whole the outlook for Amador in the way of mining was never brighter.

MISCELLANEOUS.—The St. Julian mill at Middle Bar was started last Monday, with encouraging prospects. The Volcano Gold Gravel Mining Co., operating in Volcano basin, have had a very prosperous run the past season as far as the water supply is concerned. They are operating in what is believed to be better ground than any previously worked, and the surrender of gold ought to be much larger than usual. Indeed, it is the general impression that if the claim does not pay this year there is very little hope of it ever paying. All the deep mines of the county have been troubled with an increased flow of water, which has taxed the pumping facilities to the utmost to control. The increase of water is attributed to seepage incident to the last heavy rains. Both at the Zeile and Kennedy they are having more water to contend with than at any time during the winter. The gravel claim of J. H. Hill near Oleta, which has been leased and run by outside parties, is, we are informed, turning out remarkably well. Very rich gravel has been met with the past week or two, some of it prospecting as high as \$3 to the pan. Another lot of rich ore was taken from the Middle Bar tunnel this week.

Calaveras.

MURPHYS.—*Cor. Mountain Echo*, May 6: The Central Hill hydraulic claim, owned by McCormack, Bisbee & Tower, near Murphys, is running in full blast day and night. Quite a force of hands are employed at this mine, all of whom are white laborers. Chinamen need not apply at the celebrated Central Hill mine. A good clean-up is expected, as very rich gravel is being washed at present. The Oro Plata mine, situated about one-half mile from Murphys is making an excellent showing. The mills and concentrators, which are claimed to be the most extensive in the county, are kept in motion day and night. A large number of men are employed here. The property is a remunerative one, and being very extensive, bids fair to continue so for many years.

El Dorado.

MILL.—*Georgetown Gazette*, May 8: The proprietors of the Robert Burnham mine, between Georgetown and Georgia Slide, have purchased a new five-stamp mill from Morey's foundry at Placerville, which was brought up this week. The stamps weigh 650 pounds each, and will soon be pounding away on pay ore. Monday we had the pleasure of meeting with Chas. A. Farrar and O. P. Vaughn, the enterprising and successful gravel miners at Mt. Gregory. They brought down a quantity of dust which speaks well for the quality of the pay gravel they are preparing to work in a systematic way this season. The old Fairchild claim, owned by Barklage, adjoining and on the same channel, is said to be paying largely. Adjoining is Dr. Spencer's mine, considered by these miners to be a valuable property.

Inyo.

MILL.—*Inyo Independent*, May 8: There is strong probability that John Eddy will build a new mill at Panamint within a few months. For some time past he has had a few miners at work out there prospecting, and the developments in some of his claims, more especially the Jacob's Wonder, are such as will induce him to build a mill.

BULLION.—At the beginning of the week Jack Welch brought in from Fish Springs a dab of gold bullion worth \$500. Jack and Charley Hoole have been at work all winter and spring; they have netted

\$140 a month each. They work their ore in an arastra, and appear to have enough to keep them busy as long as they may want to stick to it. Bullion from the furnace at Lookout has been arriving at Keeler for several days past. Mr. Fitzgerald writes as follows: "The furnace has been doing splendidly for the past six days. Had several mishaps in starting up on account of leak in boiler, and also had leak in water jacket, which delayed me three days."

Mariposa.

BUENA VISTA MINE.—*Mariposa Gazette*, May 8: We learn that the new shaft being sunk at the Buena Vista mine is down over 100 feet. The work is being vigorously pushed by day and night shifts. Lorenzo Alvord is the boss and the sinking and timbering is being done in the most substantial and workmanlike manner. The shaft is sunk by the side of the vein which is in sight all the way down. The ore is of a dark character containing black oxide of iron and sulphurets which indicates a close proximity to a rich body of pay rock. We understand that the mill will probably commence crushing the ore within a month's time.

MCCANN MINE.—Dr. Robinson has just returned from San Francisco where he has been purchasing some additional machinery for the mine. A new shaft has been in progress for some time, and at present the men are engaged in clearing away the rocks and leveling up the foundation for a mill-site and hoisting works. We can safely look forward to a respectable mining boom in the course of the next two or three months arising from the two mines above mentioned. There are other mines of a permanent character which are expected to crop out extensively in the course of the spring season now at hand. This mine is supposed to be a continuation of the Diltz mine. The rainy season being about over the washing off the deep dirt from the surface will soon have to be suspended. Work has been greatly retarded by the large landslides which slid in upon the main point where profitable mining was expected and necessarily had to be removed. This has all been got away and considerable wash has been done on top of the ledge which is about 45 feet wide lying in strata. The lower or fourth strata from the surface proves to be very rich, and all the dirt and vein matter which passes through the wash pays seven and eight dollars a day to the hand. The rock is piled and saved for milling purposes hereafter. Several handsome nuggets have been picked up during the winter and there are undoubtedly many more left.

Nevada.

MOORE'S FLAT.—*Nevada Transcript*, May 8: Work was resumed last Monday on L. F. K. Buch's quartz ledge. After running ten feet a promising looking vein about six inches in width was struck. There is a fine ten-stamp mill on the ledge, and the stamps will begin to crush rich-looking ore on the 15th. The mine is being run under the superintendency of J. D. Rogers, an experienced quartz miner. In the Copper Hill mine, owned principally by D. R. McKillican, who is president of the company, and superintended by A. J. Ross, a rich pocket was uncovered on Saturday last. This is not the first pocket discovered this winter. Some few weeks previous to the present writing, a \$10,000 dividend was declared. If rumors are true, \$100,000 has been extracted during the last four months. The company is constructing a wagon road to connect the mine with the stage road for the purpose of bringing in the machinery necessary to erect a mill. As soon as the mine is opened up employment will be furnished for quite a number of men. It is estimated that the road, which will be finished in ten days, will cost about \$4,000. Messrs. Hart & Bond, formerly residents of Nevada City, recently struck a promising vein in a lode bonded from Davis & Hathaway. The ledge was struck after 300-foot crosscut had been run. Free gold can be seen in the samples brought to town. Geo. Coppras, who has brought many rich specimens to town from pockets near the surface, is running a crosscut tunnel to tap the vein lower down. He has struck ore which will pay \$10 to the pan. D. R. McKillican, who has run a bed-rock tunnel under the gravel channel at Snow Point, will shortly raise an incline to tap the Blue Gravel channel. On this lead are situated the famous Derbec and Malakoff mines. During the last two weeks forty men have been put to work in the vicinity of Moore's Flat. During week days the town looks deserted, but on Sundays and stormy days it has the appearance of olden times.

CROWN POINT.—*Grass Valley Union*, May 5: The new ditch from the Idaho to convey water to the Crown Point and Badger Hill mines is completed, and Crown Point will commence the use of the water as soon as a pipe-line is laid down from the ditch to the works, which will give a pressure of 85 feet, and afford considerable more power than has been obtained by taking the water from Wolf creek. The mine continues to yield well, and the ledge at the bottom of the shafts which is 300 feet in depth, is looking very well. The ledge is seven feet wide, and makes a good showing of gold. No drifting had been done at the bottom of the shaft when the mine was formerly operated, but drifts are now being run both ways from the shaft. In cleaning out the shaft it was found that an old drift existed 20 feet below the 180-foot level which Mr. Gauthier has opened, but it was walled up at the distance of 20 feet from the shaft, and there is no knowledge existing as to how far it was extended by the former company, but it is evident that some very poor mining was done, as the miners run over the ledge, which was on the foot-wall and set their timbers upon it to hold up the drifts, and never broke into the ledge at all. The prospects of the Crown Point continue as favorable as ever, the ledge both on the 180 and 300 levels, being large and of excellent paying quality.

SLATE.—*Grass Valley Union*, May 9: Francis & Co., lessees of the Slate Ledge mine, at Forest Springs, have an excellent showing in the lower level of the new shaft, where the west drift has opened up a vein four feet in width, which prospects well in free gold. This is the largest vein ever found in the mine, and gives great encouragement as to future results. The lessees have now out sufficient ore to commence crushing, and to-morrow Perrin's mill will start up on it, and will continue to run for an indefinite time. Beside this new strike in the Slate Ledge, the tunnel in the Perrin ground, adjoining on the west, which is in a distance of over 600 feet, has opened on the same vein, the ledge at the present time showing eighteen inches in size of good milling rock. This tunnel is lower than any workings in the Slate Ledge or Noram-

bogua mines, and will afford drainage for both of these properties if extended through them.

TUNNEL COMPLETED.—The tunnel on that branch of the new Idaho ditch through which the water is to be conveyed to the Badger Hill mine, has daylight through it, and is about completed. The receiving reservoir near the end of the tunnel, from which water is to be conveyed through a pipeline to the works, requires some days work upon it to make the embankment water-proof, and in addition to this the pipe is to be connected. It is estimated that everything will be in readiness to start up work at the mine not later than the 15th inst.

Placer.

THE HAZARD.—*Placer Herald*: We learn from Col. J. H. Keown, superintendent of the Hazard drift mine, at Michigan Bluff, who has been in Auburn this week, attending to his duties as supervisor, that he is running the tunnel in the Hazard ahead in the channel using a full force and springing no time, and that the ground prospects favorably, and the outlook, all things considered, is very encouraging. The colonel has stuck to this mine with a persistence worthy of the greatest success, and it is pleasing to know that his perseverance is likely soon to be rewarded.

San Bernardino.

CALICO.—*Print*, May 9: There are few idle men in camp at present. The miners are either employed in the various mines or chloriding and prospecting for themselves. Chloriding operations are on the increase owing to the general success in this character of mining. The merchants and all other business men anticipate unusual lively times within the next two or three months, owing to the improvements going on or anticipated.

HUMBURG.—Reed & Goddard have four men at work on this mine taking out some very fine ore. They take out about one ton a day and average about 100 ounces to the ton. They ship twice a month to Barber's mill. Wm. T. Coleman & Co. are hauling monthly about 75 tons of borax from their deposits in East Calico to the Daggett depot. There seems to be no end to the supply of this commodity in their mines, which is of a high grade. Both leaching works are occupied to their full capacity in reducing low grade ore and daily adding to the bullion output. It is reported that the Red Jacket mine is about to be sold or leased to a prominent mining company.

MILL IMPROVEMENTS.—The old amalgamating pans and other machinery of the Oro Grande Co.'s mill near Daggett are being replaced by new machinery, and the entire mill is being renovated and improved. The alterations are so gradual as to only partially interfere with the operations of the mill, which is reducing ore from the Waterloo mine in West Calico. When the proposed addition of 15 stamps is made to the mill then the present force in the King mine will be considerably increased, and unusual activity will be seen in and around this valuable property.

COMET.—Woolman & Hoben, are working this old time mine. They started on a "knife blade" seam which widened out into a very large pocket, from which they took out three tons in twenty days which netted over \$700 at Barber's mill. They are now running a tunnel, which is now in about 16 feet, to tap the tunnel which contains the ore at a depth of 25 feet. They are running night and day shift. Mr. Meyers of the Pinto, is running a tunnel across the southeast end of the Little V to tap the Pinto, the shaft is down 25 feet and is sunk in an ore deposit.

THE NEW MILL.—Part of the machinery for the Runover Mining company's new twenty stamp capacity quartz mill is now on the site about 100 yards above the company's well. The work of erecting the mill will progress as rapidly as possible under the directions of J. L. Patterson, the superintendent. When the mill is completed a larger force of miners will be employed in the company's mines which will greatly enhance the business interests of the camp, and add to the present prosperity of this flourishing district.

EXCHEQUER.—Capt. Brisen and Jas. Reed are working on the Exchequer mine, which shows up well. A depth of 60 feet has been attained and ore of a fair grade has been uncovered the entire length of the shaft. Ore is now being taken from one of the tunnels. This mine is situated on a well-defined ledge of ore, and in the same belt with the famous Garfield mine, and not far from the latter. This mine would be a fine paying proposition for a company having ample milling facilities of its own.

VETO.—Cheatham & Leonard, who have had a lease on this mine for the last five months, have their men at work and are taking out about one ton a day of very good ore. They are stopping over the tunnel, which is in 60 feet, right and left, also a drift 50 feet and a crosscut 60 feet to left and 50 to the right. They ship 7 tons twice a month and average from 40 to 500 ounces to the ton.

Sierra.

BULLION.—*Mt. Messenger*, May 8: About \$75,000 in bullion went below Wednesday from the Sierra Buttes and Young America mines. Very rich quartz was shown us a few days since, which came from Keystone ravine. The ledge is from three to five feet wide.

BULLION SHIPMENTS.—*Sierra Tribune*, May 8: For the month of April the Young America mine yielded \$27,620. A dividend (No. 5) of four cents per share has been declared for that month, aggregating \$20,000. For 20 days run the Cleveland mine, with eight stamps and a working force of 17 men, turned out the snug sum of \$3500. We should have said that the mill, instead of the mine, ran but 20 days in the month, and that accounts for falling off in the yield. The Cleveland is a new mine, and is as yet being worked on a small scale. When the owners get everything in proper shape for working the mine the returns will largely increase.

Siskiyou.

SCOTT BAR.—*Cor. Yreka Union*, May 8: The latest excitement is the rich quartz lead on south fork of Mill creek, which, if it continues will make the owners rich. Peter Hansen has started a new tunnel in his Skunk hill mine. Mr. Owen Williams and Harlow Crawford have started up operations in their mine.

Trinity.

NEW RIVER.—*Eureka Times-Telephone*, May 8: Major Tonn, of New River, is en route to San

Francisco. He has purchased the interest of Ladd & Clements in the Hunter and Hoocheney claims, and intends on his arrival in the city to order a fine quartz mill with all the necessary paraphernalia, and have the same sent there immediately. He speaks very encouragingly of the mines, and is of the opinion that New River will make a good showing this summer. There are not many men in the camp just now, but considerable work is being done.

QUARTZ IN HAY FORK.—*Trinity Journal*, May 8: Messrs. Carter, Vodge, Dedrick and Thompson have built an arastra at the mouth of Big creek, Hay Fork valley, and are now doing their first crushing of quartz from their mine in that vicinity. So far they have several "stringers" of from two to ten inches in width, from which one man can easily get enough rock to keep the arastra running. We hope to hear that a satisfactory cleanup has been made soon. The water supply for hydraulic mining is holding out remarkably well, late rains serving to increase the supply. The present season is the best for many years, and a largely increased production of gold dust will result.

NEVADA.

Washoe District.

SIERRA NEVADA.—*Enterprise*, May 9: On the 520 level west crosscut No. 2 has been advanced 39 feet; total length, 466 feet. This crosscut still continues in a hard quartzite and porphyry formation with a little seepage water.

CON. CALIFORNIA AND VIRGINIA.—On the 1400 level the drift running southwest from the west drift has been extended 47 feet; total length, 801 feet. During last week 1045 tons and 1700 pounds of ore were shipped to the Morgan mill, and 1436 tons and 495 pounds to the Eureka mill. The average value of the ore milled during the week, according to assays from battery samples, was \$13.38 per ton for that crushed at the Morgan mill, and \$12.58 for that crushed at the Eureka mill. During the week bullion valued at \$35,187.58 was shipped to the office in San Francisco.

OSBISTON SHAFT.—The water now stands 2,250 feet below the collar of the shaft, and has not been lowered any during the week, as we have been engaged in cutting out a station to place a tank and donkey pump in position. Pending the progress of this work the surrounding ground is being drained down to the water line.

GOULD AND CURRY.—On the 600 level the upraise at the south line has been continued upward 39 feet; total distance above the floor of the drift, 51 feet. From the last set of timbers put in the upraise, east and west crosscuts have been started. The formation is mineralized vein matter.

MEXICAN.—On the 700 level the north bend of the joint Mexican and Union drift, running northwest from the Ophir shaft has been extended 37 feet. Total length, 159 feet. The drift running south, in Mexican ground, from this north west drift has been extended 37 feet; total length, 75 feet.

OPHIR.—On the 400 level east crosscut No. 3 running from the north drift from the old Mexican shaft has been extended 20 feet; total length, 53 feet. A west crosscut, No. 6, was started from this north drift and advanced 40 feet.

UNION CONSOLIDATED.—On the 5000 level are removing air-pipe, car-tracks and timbers from east crosscut No. 2.

Bernice District.

MILL RUNNING.—*Reese River Revue*, May 8: At Bernice the mill is running on ore from Hoyt's mine. Nothing is being done on the Williams property, although they expect to start July 1st. Mr. Williams is now shearing his sheep and looking after ranch matters, the low prices of bullion placing mining to him in the category of secondary affairs. Mr. Coruthers goes from here to Ophir on Monday, having just returned from the East, where he had taken 10 or 12 tons of ore for the purpose of reduction. Mr. Triplett brings to town specimens of blossom rock carrying free gold in abundance, which he found in the neighborhood of Hot Springs.

Columbus District.

MT. DIABLO.—*Candelaria True Fissure*, May 8: The north crosscut from the west drift on the 6th level is in 265 feet. The north crosscut from the east drift on this level is in 21 feet. The stope between the 5th and 6th levels shows a small amount of ore of fair grade. The stope above the east drift on the 5th level shows but a small streak of ore. The intermediate stope between the 4th and 5th levels look well and are giving some ore of fair grade. Considerable \$50 ore is being taken from the west drift on the 4th level. The intermediate between the 3d and 4th levels near the No. 2 winze shows 2½ feet of \$60 ore. We have a bunch of \$50 ore below the east drift on the 3d level that looks promising.

HOLMES.—In the 8th level stope we are still working in the ledge. This stope is not as large as it has been and does not produce as much ore. In the 8th level west drift, near the winze sunk by old General Thomas Company, we are stopping some good ore. This is a nice looking bunch of ore, but we cannot tell how extensive it is as but little work has been done at this point. In the winze from the 8th to connect with the 10th we are stopping. The ledge at this point looks well. In the General Thomas or 11th level we are running east. The ground is exceedingly favorable. At a short distance west of the present face of this drift we started a raise. It is now up about 40 feet. We have a nice prospect in this raise. The sulphuret winze looks well and is producing well. The hot stope has improved very much during the past week. We are getting some good ore from this stope. The stope 60 feet east of last turntable, 1st shaft level, is steadily improving. The stope 50 feet below 1st shaft level, and directly under the last mentioned ore body, is still producing well. At point 6 we are taking out some good ore.

Cottonwood District.

COBALT AND NICKEL.—*Reese River Revue*, May 8: G. T. Coruthers is in with Supt. Triplett, from Cottonwood, and speaks very highly of the cobalt and nickel mines of that district. Mr. Coruthers explains the compound term by saying that the majority of the mines carry both metals, but in some cases is by itself. Among those handling properties of this class is Lou Hanchett, who is now figuring for the sale of the Belle property, hav-

ing just returned from the East whither he had gone with a carload of ore.

Eureka District.

ORE SHIPMENTS.—*Sentinel*, May 8: During the past week ore shipments were made from the mines of the district to the two reduction works in town as follows: To the Eureka Con. work.—Marguerita mine, 1 ton; Evelin, 1; Dunderberg, 32½; Jackson, 29; Evans, 2½; Baker and Clow, 2. To the Richmond works.—Banner mine, 5 tons; Mohawk, 4; Bullwhacker, 4; Continental, 7½; Jones, 2½; Hamburg, 17; Geddes and Bertrand, 17½; Eldorado and Lemon, 3; Jackson, 12; Senator Beck and Republic, 5; Union and Charleston, 1.

Pahranaug District.

"THE INDIAN RACKET."—*Pioche Record*, May 7: Last week some quartz, showing a liberal quantity of gold, was sent to town from Pahranaug. The quartz was said to have been brought there by an Indian, who was afterwards followed, and the place discovered, about 80 miles from Hiko. A four-horse team and several ranchers started for the Breifogel country, where the Breifogel ledge had been found to a dead certainty, and where they were going to load up with gold, return home and remain idle the remainder of their days. They got within forty miles of the place with their team, and being unable to get any farther with the wagon, they all returned home, with a small piece of copper-stained metal. The gold quartz showed the gold very freely, and from whence it came we know not, but this Indian racket is getting to be too ancient. We have lost confidence in it.

Pennsylvania District.

MOVING ALONG WELL.—*Pioche Record*, May 7: Affairs in this district are moving along nicely. Assessor McFadden, who took a trip there, says the mill is doing good work and turning out bullion rapidly. The mill is not of sufficient capacity, being only a five-stamp. The ledge in the mine is three and a half feet wide, and is taken out and shipped to mill without sorting. It has been satisfactorily demonstrated to those interested that it is a good paying proposition. Mr. Barton certainly deserves success.

Tuscarora District.

GRAND PRIZE.—*Times-Review*, May 6: The north drift from east crosscut in the 200-foot level extended 27 feet during the week, and east crosscut extended 11 feet. Stopes not producing much ore. Mill has been started up to work what ore is on hand.

NAVAJO.—North drift on the east vein from No. 5 crosscut, 350 foot level, has been extended seven feet.

BEILE ISLE.—North drift from east crosscut No. 1, 450-foot level, has been extended 16 feet.

Yankee Blade District.

AN OLD CAMP.—*Virginia Enterprise*, May 7: This old mining district, situated three or four miles north of Austin, in Lander county, was quite noted in the early history of the Reese River mining excitement, twenty years ago, but it has since fallen into comparative obscurity. There are only about half a dozen mines in the district now being practically worked, yet the ore extracted is of the rich antimonial silver character, worth from \$300 to \$3,000 or more per ton. The veins are narrow, like those of Austin, from two to ten inches thick, but at the depth of 300 feet or less a large amount of water is encountered, the drainage of which is too costly under present existing arrangements. At some future time some company of capitalists will sink a deep shaft and put in a big Cornish pump which will drain the whole basin, giving ample access to all of the many small rich ledges. Yankee Blade will then be worked to advantage and yield a goodly number of silver bricks daily. It is one of the many districts in this State which are waiting for capital to develop and bring out their resources properly. The *Austin Reville* says: At last the efforts persistently made in the Yankee Blade district to uncover the ore bodies believed to exist there seem upon the eve of fulfillment. David Todd, who has grown gray whacking at these rocks, has struck it big on the western slope, and now has exposed to view at a depth of 70 feet a body of mineral two and a half feet thick which will go 600 ounces to the ton.

ARIZONA.

SANTA RITA PLACERS.—*Tucson Citizen*, May 8: When the great placer mines of the Santa Rita mountains are worked in systematic manner by associated capital it is believed that an enormous amount of gold will be brought out from its hidden places to do service for mankind. The development of the water supply for hydraulic mining is the first requisite of the proper working of the mines and there is a strong probability that properly directed enterprise will secure the desired liquid in sufficient quantities not only for mining purposes, but for irrigating agricultural lands through the proper storage of the waste water.

COLORADO.

LAKE COUNTY MINES.—*Leadville Herald Democrat*: The new Pittsburg property during the first three months of the current year yielded \$230 worth of ore. The Amity lode, controlled by Geo. O. Keeler, and situated on the west side of the Arkansas river, has recently shipped some very fine ore to the American smelting works. The developments from the McHarg shaft on the Morning Star now show 10 ft. of fine sand ore. The working force of the mine has been increased during the past sixty days, and the pay-roll now contains about 50 names, while the lessees employ about 75 men. Excellent progress is being made in the placing of the new \$10,000 hoisting and pumping plant on the Adams shaft, on a Yankee hill. Operations will be resumed with a full force of miners at the Brookland shaft, next Sunday night. The pumping plant in this shaft is now in the best possible condition. The St. Louis parties who recently purchased the Katy and Midnight lodes, on Little Ella Hill, are losing no time in putting their properties in a producing condition. Since the purchase, which was made less than a fortnight ago, they have erected a shaft-house, and to-day a hoisting engine was shipped from Denver for the Katy mine. The La Plata Mining and Smelting Company, during the first half of March, received 400 tons of ore from the mine of the company, and 1900 tons of other sources. It smelted 2000 tons of ore, and produced

200 tons of bullion, containing about 30,000 ounces of silver. During February, the company received 750 tons of ore from its mines, and purchased 2850 tons. The amount smelted aggregated 3400 tons, producing 374 tons of bullion, containing 60,000 ounces of silver. The La Plata smelter has been compelled to close down, being unable to secure the particular ores required to make economical smelting charges. Several other establishments have also reduced the number of furnaces in blast, being unable to secure ores from the mines with which they have contracts, on account of the bad roads. The Pueblo smelter is also suffering on the same account.

DAKOTA.

TIN MINES.—*Cor. Denver Tribune-Republican*, May 8: The Etta Tin mining company of the Black Hills in Dakota are now running their extensive reduction works night and day, employing a large number of men in mining the ore and running the works, producing concentrated tin ore that assays 50 per cent metallic tin, and their monthly shipments of these concentrates average \$40,000 in value. Mr. Robert A. Little of Detroit and Mr. James Campbell of Chicago have purchased within the past two weeks nine claims on tin ore veins, paying \$50,000 for them, and the deepest work done on any of these claims was 35 feet, showing that these claims are very valuable. Parties from the East have lately purchased from Moore and Blackmore several claims in Warren Gulch, seven miles west of Custer, for \$45,000, and sales of single claims are being made nearly every day of from \$1,000 to \$5,000 per claim. Parties from Scranton, Pennsylvania, have purchased claims and are now erecting works for the reduction of the ore, and the time is not far off when the Black Hills of Dakota will be shipping tin pigs by the ton to the different markets of the United States, thereby adding one more very valuable mineral resource to the many that we can boast of now here in the West.

IDAHO.

SOUTH SIDE NOTES.—*Coeur d'Alene Record*, May 5: The Miller claim is yielding well. One hundred and seventy-six ounces were taken from the Myrtle claim last week. Will Hiren has gone to Spokane Falls to attend the spring and summer terms of the business college. Although both Myrtle and Delta are seemingly very quiet, there is a large amount of work going on in and near both places. Buzzard & Co. have nearly finished cleaning bed-rock on the Montana Bar claim after three weeks' pining. They appear to be well satisfied with results so far obtained. Commissioner Human issued warrants to a number of road men Saturday who have completed their contracts. Most of them have been purchased at the bank, the highest market price being paid. Recent promising quartz discoveries have considerably strengthened the belief which many have held for some time that the South Side will yet compare favorably with other sections of the Coeur d'Alene in the production of precious metals from quartz. Jake Herdier & Co. have purchased Tom Heaney's and J. H. McCaulay's interest in the three claims in Trail gulch, above the ground owned by the Nickerson brothers. It is good ground and will continue to be worked to advantage under the new management. Booth & Ashman, who have valuable placer ground in Potosi gulch, and have been pining for several weeks past, have commenced cleaning bed-rock. If we may judge from what the claim has already produced we may expect soon to learn of an exceptionally fine clean-up. Three hundred and twenty-eight ounces of gold were bought at the Delta bank last week, one hundred and seventy-six ounces coming from the Myrtle claim, the bonanza placer property of Trail creek. At \$16 an ounce Banker Atchison must have paid out \$5,248 in exchange for the precious yellow.

HEAVY SHIPMENTS.—*Wood River Times*, May 5: During the past few days the ore which accumulated at the Idahoan mine during the few weeks of impassable roads has been literally pouring into Hailey, where it is sampled and shipped. Last Saturday 80,000 pounds were received; yesterday, 60,000 pounds; to-day, about 55,000 pounds. This will continue for some days, as there is an accumulation of over half a million pounds of ore at the mine which Superintendent Havens intends to market at once, in order to get it out of the way, and permit him to continue his extensive operations unobstructedly.

FROM SMOKY.—George Montgomery called to-day. He tells the *Times* that Smoky is steadily coming to the front. All the mines are being worked or preparations are being made to work them. The Carrie Leonard is a splendid property. A large body of rich ore was struck in it last Thursday.

MONTANA.

AROUND HELENA.—*Independent*, May 6: The mining boom in the territory tributary to Helena is being inaugurated early in the season. The properties already developed are being worked with rich results, and new locations are being made in various districts, while properties in all directions are passing into paying development, and will soon be paying tribute to Helena, whose railway system is reaching out to grasp the business. Work on the Mountain Queen, near the head of Clancy creek, will be commenced this week by drilling a tunnel running in on the vein near the base of the mountain. Work is being pushed vigorously on the Consolidated Red Mountain tunnel with fine indications. Results from the astrata run on gold ore from the Lexington Chief vein are very satisfactory to the owners. A ten-foot gold bearing ore vein is reported from the Cora, in the McClellan district. About three tons of gold ore per day are being taken out of the Grant mine, located about seven miles southeast of Helena, and if immediate future developments continue as promising as the past, a three-stamp mill will be put in early this season. The mining outlook was never so promising as now.

THE COLUSA.—*Butte Miner*, May 8: Manager Raunheim is constantly opening up new bodies of ore. Developments are continuing on a large scale, but no ore will be hoisted for the present. Connection with the works of the Liquidator mine (recently acquired by the Montana Copper Company) was made during the past week. The ore bodies in the Liquidator mine are very large and of an excellent quality.

THE GOLDEN RULE.—This mine is situated west of the Lexington, and is producing some fine ore.

It is owned by Col. Estes *et al.*, who have a large force of men constantly extracting ore. It was reported that a large body of ore had been exposed in the east drift on the lower level, and orders were given to crosscut on the hanging wall in the west drift.

THE PARROT.—This mine is making its usual shipments of over 300 tons of high grade copper ore, which keep their large smelter supplied. The mine has produced more ore than any of the surrounding properties. Superintendent Tibbey has the mine worked systematically.

THE MOUNTAIN CHIEF.—This mine has lately made several additions to its hoisting capacity, and is enabled now to ship 60 tons of high grade ore a day which is sampled at the Montana Copper Company's Works.

THE WANDERER.—This mine is owned by C. J. McSherry *et al.* The shaft is now down about 140 feet, and it is expected that at the depth of 160 feet a crosscut will be run in about 25 feet to cut the lode.

THE NORTH STAR.—This mine is owned by Dr. Mussigbrod *et al.* The company is now making preparations to place new hoisting works on the mine.

OREGON.

RICH STRIKE.—*Bedrock Democrat*, May 3: Only one week since H. P. Nitcher and partner, the former porter at the store of J. Durkheimer, left this city on foot, lugging their camping outfit and miner's tools, on a prospecting tour, and, wending their way to the west of the city in the vicinity of the snow-capped peaks so plainly visible from this city, their efforts were rewarded a few days ago by their discovering the long-looked-for extension of the "Tom Paine" mine, which has always been noted for its great richness. The parties came to town yesterday to properly locate the same and make preparations for the working of the mine. We were shown a sample of the ore and must say it is marvelously rich, the gold cropping out all over the rock. We would not be surprised if they had struck a "pocket" that perhaps might equal the \$10,000 pocket, once struck in the parent vein of the "Tom Paine."

UTAH.

ALTA.—*Cor. Salt Lake Tribune*, May 7: The Frederick is working but few men, owing to the want of coal. Superintendent Harkness seemed to be much pleased with the work performed in the Frederick, last season, and the general outlook of the Frederick and Crown Prince Mining Company's property, and he is anxiously waiting for the opening of the road in order to ship his coal and start the machinery again and increase the present force of men. The Flagstaff mine, which has been lying idle for years, started again last summer, under the management of Professor Vincent, who is now in England. Dr. Bredemeyer, who is here now on his tour of inspection, is acting manager during the absence of Professor Vincent. This mine has been running all last winter, and is still running under the foremanship of Mr. John Bright and a force of twelve men. The seventh level is in forty feet; twenty-three feet further will make connection with the winze sunk in the large body of iron ore. The main tunnel is in ninety feet. The Vallejo mine is looking fine. There are at present in the mine about 300 tons of ore ready for shipment and a large body in sight. I was informed a few days since that the foreman, Mr. Gundison, will have to stop the extraction of ore on account of surface water. The Vallejo mine has been doing well under the able management of Charles Reed. Mr. Miller, one of the contractors of the Flagstaff tunnel, returned here on the 21st of April with two miners, in the place of the unfortunate Butterwood and McDonald. The contract is for 300 feet. They have run up to this morning 80 feet, and he is doing his utmost to forward the work with all possible speed. The New Emma is still laying idle for the want of coal. There is a small supply of coal on hand, but Superintendent Cullen don't want to start the mine too early for fear the supply will be exhausted before the tramway is open.

REVIEW.—*Salt Lake Tribune*, May 7: The bullion receipts in this city for the week ending May 5th, inclusive, amounted to \$123,776.49; ore, \$28,327.01; a total of \$152,103.50. The previous week the receipts were \$175,938.17, of which \$159,880.18 was bullion and \$16,057.99 was ore. The output of the Ontario for the week ending May 7th, 1886, was 17,096.38 ounces of bullion and \$13,116.72 of ore. For April, 1886, 276 ounces bullion and \$1,408 bullion slugs. The output for the four months of the present year foots up \$622,657.99, reckoning silver as closely as it can be reckoned on the fluctuating market. From this two regular monthly dividends of \$75,000 each, or \$300,000, have been declared and paid. The roads are improving at the Park, and ore shipments have been begun from both the Ontario and the Daly. The product of the Daly for the week was eight bars of bullion, 11,696.13 ounces; for April, 43,155.68 ounces; total for this year, \$171,727.75, including ore sales, which have been stopped for a month by bad roads, but will now be resumed. Ore shipments have begun from the Cave mine, Beaver county. The base bullion receipts for the week amounted to \$12,550; fine bars, \$17,096. The Hanauer smelter product for the week was \$30,685; that of the Germania, twelve cars, \$28,629.16; of the Pascoe, \$2,240—a large total for the smelters. The Stormont sent up \$3,890 in silver bars during the week. Ore receipts were: Queen of the Hills, \$4,770; silver and lead ores, \$7,950; lead and silver, \$13,607.01.

THE EMMA MINR.—A London cable received yesterday by Mr. Cullens, given in last night's *Democrat*, directs him to resume operations at once on the Emma mine at Cottonwood, and work will be commenced immediately and vigorously prosecuted during the season. Operations were suspended last December on account of dangerous snow-slides. This celebrated mine has already produced upwards of \$7,500,000, and as yet hardly prospected. The vein is from 200 to 300 feet in width, and there is every reason to believe that the former yield will prove but a bagatelle to the future output. The mine is in an excellent condition for working. The tunnel which is 1740 feet in length, taps the vein at a depth of 750 feet, and at the end a shaft has been sunk 225 feet. It will require four or five days to pump out the water, when drifting at the second level and sinking of the shaft will be commenced.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific States.

From the official report of U. S. Patents in Dewey & Co.'s Patent Office Library, 262 Market St., S. F.

FOR WEEK ENDING MAY 4, 1886.

341,216.—ROAD-CART—M. L. Bergman, Buena Vista, Ogn.
341,091.—DISINFECTANT—A. P. Bouton, S. F.
341,099.—AIR COMPRESSOR—Geo. E. Dow, S. F.
341,323.—CIGAR—E. Ehlin, S. F.
341,001.—FOUNTAIN PEN—E. J. Hall, S. F.
341,032.—HORSE BOOT—J. A. McKerron, S. F.
341,049.—PICTURE MOLDING MACHINE—Samuel A. Perry, S. F.
341,429.—PAPER CURRENCY—I. M. Phelps, Shastat, Cal.
341,165.—CONVERTIBLE DRILL PRESS—L. H. Pierson, S. F.
341,055.—SAW GUIDE—J. A. Rolb, San Jose, Cal.
341,350.—PENHOLDER—S. A. Rogers, Austin, W. T.
341,056.—COPYING PRESS—Samuel & Breidenstein, S. F.
341,292.—CAR COUPLING—A. W. Van Dorston, Portland, Ogn.
341,297.—ENVELOPE—F. R. White, S. F.
341,121.—GRAIN SEPARATOR—David Young, Stockton, Cal.

NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates and in the shortest possible time.

Mining Share Market.

There has been quite an active market for mining shares during the week, with advancing prices. Our stock tables show what the fluctuations have been. The Comstocks have advanced from five to twenty cents per share.

The Young America Mining Co., of Sierra county, Cal., paid a dividend of four cents per share, or \$20,000 last month. This makes \$50,000 to date.

The Elk Horn Mining Co., of Montana, paid its twenty-second dividend on the 30th ult., amounting to \$5000, making \$115,000 to date.

The Mary Murphy Mining Co. has recently paid its first dividend of five per cent. The mine is in Chaffee county, Colorado.

The bullion shipments from the Calico district in San Bernardino county from January 1st to April 18th amounted to \$2,207,000.

The assessment of the Hale and Norcross levied this week is number 90.

Bullion Shipments.

We quote shipments since our last, and shall be pleased to receive further reports:

Silver King, May 8, \$17,000; Alice, 6, \$27,200; Oro Grande mill, 9, \$5825; Odessa mill, 9, \$12,000; Barber's mill, 8, \$6000; Mt. Diablo, 6, \$4447; Alice, 4, \$14,608; Hanauer, 4, \$7490; Pascoe, 4, \$2240; Germania, 4, \$9066; Hanauer, 5, \$5455; Stormont, 5, \$3890; Queen of the Hills, 5, \$1060; Germania, 6, \$4366; Alice, 6, \$14,078; Germania, 7, \$4335; Hanauer, 7, \$8530; Stormont, 7, \$1820; Alice, 8, \$13,136. At Salt Lake, Wells Fargo & Co. received in bullion last week \$29,646; McCormick & Co. \$49,535; T. R. Jones & Co. \$44,236; and Union National bank \$28,666. The banks of this city report the receipt for the week ending May 5th, inclusive, of \$123,776.49 in bullion and \$28,327.01 in ore, a total \$152,103.50. Young America (for April), \$27,620; Cleveland, May 8, \$3500; Con. Virginia & California, 8, \$35,137.

New York Metal Market.

Telegraphic advices dated May 13th, give the following New York prices:

BORAX—6½% @ 7½%
BAR SILVER—\$100½ per oz.
COPPER-LAKE—\$11.37½
IRON—No. 1, \$17 @ 18.50; No. 2, \$16 @ 16.50.
LEAD—\$4.85 @ 4.95.
QUICKSILVER—43 @ 43½¢ lb.
The following is the latest from the "New York Metal Market Report":
COPPER—Neglected; Lake offered at 11.30c. Transferable Notices (Lake) offered at 11.30c; Transferable Notices (Chili Bars) offered at 4.40c.
LEAD—Quiet and weak at 4.70 @ 4.80c. Transferable Notices (Domestic) issued at 4.75.
SPELTER—Steady at 4.45 @ 4.65c. Transferable Notices (Domestic) issued at 4.55c.
TIN—More active at 20.80 @ 20.85c. Transferable Notices issued at 20.75c.
TIN PLATE—Dull. Transferable Notices issued at 4.35.
IRON CERTIFICATES—Dull and nominal. Transferable notices (May delivery) issued at 17.
SILVER—New York, 100½ per oz. London, 45½d.
MAKER'S PRICES—At tidewater, 100 ton lots of listed irons (when brand is specified) range nominally about as follows: Lehigh, Grade No. 1, \$18 @ 19.50; No. 2, \$16.50 @ 17.50; Grey Forge, \$15.50 @ 17.00. Hudson River, Grade No. 1, \$18 @ 19; No. 2, \$16.50 @ 17.50; Grey Forge \$15.50 @ 16.50. Southern, Grade No. 1, \$18.50 @ 19; No. 2, \$17 @ 17.50; Grey Forge \$16 @ 17.
Prices generally ruling for metals not regularly dealt in on call at the N. Y. Exchange, covering extremes of buyers' and sellers' views. All prompt delivery.—Australian Tin, May 7th, \$20.85 @ 20.95; Billiton Tin, \$21.05 @ 21.25; Banca Tin, \$21.20 @ 21.35; Baltimore Copper, \$9.90 @ 10.15; Orford Copper, \$9.90 @ 10.15; P. S. C. Copper, \$9.90 @ 10.40; Foreign Lead, \$4.70 @ 4.85; Foreign Spelter, 4½ @ 5½.

TATUM & BOWEN,

25 to 31 MAIN ST., SAN FRANCISCO, and 91 and 93 FRONT ST., PORTLAND, OREGON.

We have recently furnished the Contractors the Machinery for

LA TRINIDAD
(300 Tons per Day)

—AND—

SILVER QUEEN
(100 Tons per Day).

These Mines are Located in Mexico and owned in London.

The Process is the Wet Concentration and the Plants are, without doubt, the most Substantial and Complete ever built.

We are Sole Agents for the Celebrated

ALBANY

Lubricating Compound,
Cylinder and Lubricating
OILS.

We make a Specialty of Lubricants for Export and Home Consumption.

1850. 1885.

RANKIN, BRAYTON & CO.,
...BUILDERS OF...
MINING MACHINERY.

San Francisco: 127 First Street. Chicago: 100 N. Clinton. New York: 145 Broadway.

PLANTS FOR GOLD AND SILVER MILLS, embracing machinery of LATEST DESIGN and MOST IMPROVED construction. We offer our customers the BEST RESULTS OF 35 YEARS' EXPERIENCE in this SPECIAL LINE of work, and are PREPARED to furnish from SAN FRANCISCO or CHICAGO, the MOST APPROVED character of MINING AND REDUCTION MACHINERY, adapted to all grades of ores and SUPERIOR to that of any other make, at the LOWEST POSSIBLE PRICES.

We are also prepared to CONSTRUCT and DELIVER in COMPLETE RUNNING ORDER, in any locality, MILLS, CONCENTRATION WORKS, WATER JACKET SMELTING FURNACES, HOISTING WORKS, PUMPING MACHINERY, ETC., ETC., of any DESIRED CAPACITY.

WATER JACKET SMELTING FURNACES

For COPPER and ARGENTIFEROUS LEAD ores of NEW and ORIGINAL DESIGNS, covered by LETTERS PATENT. No other Furnaces CAN COMPARE with these for DURABILITY, and in CAPACITY for uninterrupted work, MORE THAN 150 of them are now RUNNING in various parts of THIS COUNTRY, as well as many in FOREIGN COUNTRIES, giving results NEVER BEFORE ATTAINED as regards CONTINUOUS running, ECONOMY of fuel, AMOUNT and QUALITY of BULLION produced. These CLAIMS have been PROVEN BY RESULTS in ANY NUMBER of INSTANCES, and the GREAT SUPERIORITY of this SYSTEM of smelting ores DEMONSTRATED BEYOND QUESTION. COMPLETE PLANTS furnished to order of any CAPACITY, with ALL IMPROVEMENTS that experience has DEMONSTRATED as VALUABLE in this class of work.

Beyond question the cheapest and most effective machine of the kind now in use adapted to all grades and classes of ores.

This machine has been THOROUGHLY TESTED for the past TWO YEARS, under a GREAT VARIETY of CONDITIONS, giving most EXTRAORDINARY results FAR IN ADVANCE of anything EVER BEFORE REALIZED. A recent COMPETITIVE TEST at the Carlisle Mine in Mexico, showed an ADVANTAGE OF OVER 30 PER CENT in favor of THE DUNCAN. The amount SAVED OVER THE TRUE being sufficient to PAY THE ENTIRE COST of the machines EVERY MONTH of the YEAR. One of its MOST VALUABLE features is as an AMALGAMATOR. It saves all THE AMALGAM GOLD and SILVER that ESCAPES the BATTERIES, PANS or SETTLERS, making the machine worth MORE than ITS COST for THIS PURPOSE ALONE.

Baker's Mining Horse Power.

Possessing all the requirements of a first-class hoist and affording means for the continuous operation of a Pump or Blower, without interfering with a hoisting apparatus. It is made entirely of iron, no piece weighs over 300 pounds. At the ordinary speed of a horse, a 1,000-pound bucket of ore may be raised 120 feet per minute. The hoisting-drum is under the complete control of the man of the shaft, and is capable of carrying 500 feet of five-eighths steel rope. SEND FOR CIRCULAR.

END FOR CIRCULAR.

IMPORTANT TO GOLD MINERS! SILVER-PLATED AMALGAMATING PLATES FOR SAVING GOLD

IN QUARTZ, GRAVEL AND PLACER MINING.

Warranted the Best Made, Durable and Satisfactory. Full weight of silver and best quality of plating guaranteed.

BEST SOFT LAKE SUPERIOR COPPER USED.

3000 Orders filled. Reference first class. Prices the very lowest. Have received every Medal awarded on the Pacific Coast for Mining Plates. Old Mining Plates Bought, Replated, or Gold Separated.

SAN FRANCISCO GOLD, SILVER AND NICKEL PLATING WORKS, 653 & 655 Mission St., San Francisco.
E. G. DENNISTON, Proprietor.

These Plates can also be procured of JOHN TAYLOR & CO., Dealers in Assayers' and Mining Material, 112 to 118 Pine St.

NOTICE.—Mining men are cautioned against purchasing inferior quality of Silver-Plated Mining Plates now being manufactured in this city. There has been a general complaint by purchasers that these plates proved defective in plating and short in weight of silver, assays showing great deficiency in silver guaranteed. Thin, light plating looks the same as heavy, but has no durability. Good plates can be furnished at same price these poor plates cost.

THE FOOS MANUFACTURING CO., - - Springfield, Ohio

JENKINS PATENT VALVES.

Gate, Globe, Angle, Check and Safety.

Manufactured of BEST STEAM METAL. We claim the following advantages over other Valves and Gauge Cocks now in use:

1. A perfectly tight Valve under any and all pressures of steam, oils or gases.
2. Sand or grit of any kind will not injure the seat.
3. You do not have to take them off to repair them.
4. They can be repaired by any mechanic in a few minutes.
5. The elasticity of the Disc allows it to adapt itself to an imperfect surface.

In Valves having ground or metal seats, should sand or grit get upon the seat it is impossible to make them tight except by regrinding, which is expensive if done by hand, and if done by machine soon wears out the valve, and in most cases they have to be disconnected from the pipes, often costing more than a new valve. The JENKINS Disc used in these Valves is manufactured under our 1880 Patent, and will stand 200 lbs. steam. Sample orders solicited. To avoid imposition, see that Valves are stamped "Jenkins Bros." ADAMANTINE Shoes, Dies and Crusher Plates

We manufacture the above Adamantine Shoes, Dies and Crusher Plates. They are in use on the hardest quartz in the United States and South and Central America, and have been

ADAMANTINE. for the last ten years; we warrant them to out-wear three (3) sets made of any other metal, and many report that they last from 4 to 8 times longer than any other make. They never break AT THE SHANK, and the wear is so light that little or no foreign matter gets mixed with the crushed ore.

Also CHROME CAST STEEL for Mining and General Use, of the finest quality.

For further particulars, address

CHROME STEEL WORKS,

H. D. MORRIS, Agent, 22 Fremont St., San Francisco.

When ordering, a rough sketch, with full dimensions, is all that is necessary.

CALIFORNIA

ARTIFICIAL STONE PAVING CO.

(SCHILLINGER'S PATENT.)

—FOR—

SIDEWALKS, GARDEN WALKS, CORRIDORS, OFFICES, CARRIAGE DRIVES, STABLES and CELLAR FLOORS, KITCHENS, Etc.

The Courts here and in the East have decided that Artificial Stone Pavements with plastic concrete and in detached blocks, are infringements on the Schillinger Patent; and also, that when the plastic material is blocked off with a trowel and cut through far enough to control the cracking caused by shrinkage, that such pavement is in law the same as if laid in detached blocks, and is an infringement of the patent. All property-owners having such pavements laid without the license of the above Company, will be prosecuted.

SAN FRANCISCO NOVELTY AND PLATING COMPANY, Removed to 108 First St.

JUSTINIAN CAIRE, Dealer in Mining Material, Agent, 521 & 523 Market St., San Francisco.

NOTICE TO MILL MEN.—All our plates are guaranteed to have the Full Weight of Silver agreed upon, and are all tested before leaving our Works, thereby avoiding the complaints about light-weight, made so often formerly before our starting in this branch of business. PLATES CAN BE FURNISHED AT ANY PRICE REQUIRED.

JAMES LEFFEL'S Mining Turbine Water Wheel.

These Wheels are designed for all purposes where limited quantities of water and high heads are utilized, and are guaranteed to give more power with less water than any other wheel made. Being placed on horizontal shaft, the power is transmitted direct to shafting by belts, dispensing with gearing. Estimates furnished on application for wheels specially built and adapted in capacity to suit any particular case.

Further information can be obtained of this form of construction, as well as the ordinary Vertical Turbines for Wooden Penstocks and in Iron Globe Cases, free of cost, by applying to the manufacturers,

-NATURAL- CHALYBEATE MINERAL WATER.

A TONIC THAT HAS NO EQUAL FOR BUILDING UP THE SYSTEM. IT CURES
Impoverished Condition of Blood, General Debility, Green Sickness (or Chlorosis),
Chronic Dysentery, Dyspepsia, Neuralgia, Skin Diseases, Etc.

Obtained from a Spring near Glenbrook, Lake Co., Cal.

The Chemical Analysts show the contents in a U. S. Wine Gallon to be as follows:
Sulphate of Protoxide of Iron, 43.775; Sulphate of Magnesia, 9.477; Sulphate of Lime, 6.516; Sulphate of Alumina, 2.940; Sulphate of Sodium, 123; Chloride of Sodium, 2.138; Oxide of Iron, 154.

W. T. WENZEL, Analytical Chemist, San Francisco.
Large numbers of the leading physicians of this State, whose attention has been called to the CHALYBEATE, recommend it. For sale by all Druggists.

M. MACDONALD, General Agent, 19 Montgomery St., San Francisco.

CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding homastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 (XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

JOHN F. LOHSE, SEC'Y.

Office, No. 230 California Street - - San Francisco, Cal.

THE CONSUMERS' COMPANY.

VULCAN B B AND AJAX.

The Best LOW GRADE EXPLOSIVES in the Market.

SUPERIOR TO BLACK OR JUDSON POWDER.

Vulcan Nos. 1, 2 and 3,

The Best NITRO-GLYCERINE POWDERS Manufactured.

SPECIAL INDUCEMENTS IN PRICES.

AJAX and VULCAN B B POWDERS are Unequaled for Bank Blasting and Railroad Work.

Caps and Fuse of all Grades at Bottom Rates.

VULCAN POWDER CO.,
218 California Street, San Francisco, Cal.

THE GIANT POWDER COMPANY

Manufacture Three Kinds of Powder, which are acknowledged by all the Great Chemists of the World as

The Safest and Strongest High Explosives in the Market.

GIANT POWDER or DYNAMITE,
Of Different Strengths as Required.

NOBEL'S EXPLOSIVE GELATINE," which contains 94 per cent of Nitro-Glycerine, and GELATINE-DYNAMITE, Stronger than Dynamite and even Safer in Handling.

JUDSON POWDER IMPROVED.

FOR RAILROADS AND LAND CLEARING. Is from three to four times stronger than ordinary Blasting Powder, and is used by all the Railroads and Gravel Claims, as it breaks more ground, pulverizes better and saves time and money. It is as dry as the ordinary Blasting Powder and runs as freely.

BANDMANN, NIELSEN & CO.,

HOOD'S FOUNDRY COKE.

Consumers are respectfully informed that owing to inferior brands of Coke having been sold in this and other countries under the name of "Patent Coke," the Glamorgan Coal Co. (Limited), Cardiff, in May, 1884, abandoned the title of "Patent Foundry Coke," substituting that of "Hood's Foundry Coke."

This Coke is exclusively used by the Selby Smelting and Lead Co., Union Iron Works, Professor Thomas Price, and other consumers here. Large quantities are regularly forwarded to Copper Smelters in Arizona and New Mexico, and also to consumers in Nevada and Salt Lake. The undersigned are the SOLE IMPORTERS of the above Coke, which is for sale in quantities to suit purchasers.

VOLUME LII
Number 21

The Frisbee-Lucop Quartz Mill.

We mentioned last week that a machine for pulverizing quartz, just being introduced on this coast, had been set up and in operation at the Pacific Iron Works, in this city. This is the Frisbee-Lucop mill, which we have since seen in operation. It has been at work in the East for some years, grinding phosphates, but has been improved and adapted more particularly for quartz work. We present herewith engravings of this mill. It is a centrifugal roller mill, in which the rollers revolve on their axis and are carried around in a vertical plane on the inner periphery of a heavy ring of hard steel, set vertically inside of a suitable casing, against which they exert a centrifugal force of 1800 to 2000 pounds each, according to their speed. There are two rollers, which are propelled by cylindrical or curved drivers, as may be preferred, and held in place by a pair of disk plates, which are bolted to the arms on either side. This form of construction allows the rollers to lie loosely in place and to move from the face of the ring toward the shaft, so as to pass over pieces of iron or steel that may accidentally enter the mill. An automatic feed is attached, and every mill is complete and ready for the belt when shipped. The wearing parts, which are the ring, rollers and drivers, weigh altogether about 700 pounds, require no fitting, and are readily replaced when worn out. The

depending upon the number of the screen used or the velocity of the air current, when the latter is used, and there are no tailings to be returned to the mill for regrinding, thereby avoiding the expensive and troublesome elevating and screening machinery necessary where part of

outward through the screens, and discharge the finished product through a chute, which passes downward through the bed-plate, from the casing on each side of the mill, and, for amalgamation, the pulp may drop directly on plates or be conducted to pans. Where the product

hinged to the lower at one side, and is easily raised, so as to give free access to the interior of the mill, for examination and replacing worn parts. A new feature in these mills is attaching a revolving screen of coarse mesh to the shaft inside of the fixed screens, which prevents

any pieces of iron or large pieces of rock from coming in contact with the fine screen, but does not prevent the finished product from passing freely. This revolving screen is entirely unnecessary in quartz or other hard material, and is only used when clay, cement, talc, or some such soft material is ground, when the mill is filled *entirely full* of the rock.

Referring to the cuts, Fig. 1 shows the mill closed; Fig. 2, with upper half of the casing raised, showing the ring in place, one of the disks partially broken away, exposing a portion of one arm, a roller and driver, and also the propeller fans. Fig. 3 is a vertical transverse section through the ring rollers, drivers, arms, etc., fully showing the automatic feed.

The reference letters (Fig. 3) show: A, bed-plate; B, casing; C, C, C, keys which hold the ring, D, in place, and by which it is adjusted to position; D, ring; E, E, arms; F, F, drivers; G, G, rollers; H, opening through which the rock is fed to the mill; J, cam on feed shaft which strikes the tappet, L; K, feed shoe; M, adjustable screw for graduating the feed; N, hand wheel by which the screw, M, is turned; O, suspension rods for K; P, a

FIG. 1. THE FRISBEE-LUCOP QUARTZ MILL.

FIG. 2. INTERIOR VIEW OF THE FRISBEE-LUCOP MILL.

FIG. 3. TRANSVERSE SECTION OF MILL.

amount of wear of these renewable parts depends upon the hardness of the material ground, but it is claimed that the loss will, in any case, be less than in stamp mills on the same substances, as there is no loss by breakage. All substances, of whatever kind, when ground, leave the mill in a finished state, their fineness

which the material, as fed into the mill, is distributed around the inner periphery of the ring, in the path of the rollers, insuring an equal amount of work at every point on the face of the ring.

Outside the screens is another pair of propeller fans, which cause a current of air to pass

fan or other method of causing a current of air to pass through the mill. In this case there are openings in the bottom of the casing for the admission of air. The casing is divided horizontally, and the upper and lower halves are held together by hinged bolts, in slots cut in the flange of each section. The upper half is

spring, which bears against the tappet, L, and throws the feed shoe back to its place after the cam passes the tappet; R, a square projection, fitting square hole in disk plate, by which the cylindrical driver is prevented from turning S, a portion of disk plate T, T, T, holes for (Continued on page 341.)

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

Xanthates.—No 2.

[Written for the MINING AND SCIENTIFIC PRESS by C. H. AARON.]

In working up my "new copper assay" I was a little surprised to find that the reaction was different from that which occurs in the cases of some other metals, as nickel and cobalt for example. With copper, whether in ammoniacal solution or as neutral sulphate, chloride, etc., the precipitate is not a homologous of the precipitant; the reaction is not then a simple metathesis.

According to Regnault, potassium xanthate consists of one molecule of potassium oxide and one of xanthic acid. If this copper compound were of similar composition, it would contain rather less than 21 per cent of copper, but it contains very close to 33 per cent, which agrees with the hypothesis that it consists of two molecules of copper oxide and one of xanthic acid, or it might be two of copper dioxide, one of water and one of xanthic acid, and in order to understand the reaction by which it is produced it was necessary to know which.

Not having the means of analyzing such a substance as xanthate, I was at a loss to make the matter out, the more so as nickel and cobalt give compounds containing the correct proportion of metal for homologues of the precipitant. The hypothesis of a hydrate did not strike me at first, nor favorably at last, and the other requires the assumption that two molecules of the precipitant are decomposed for one of the copper salt, and then the question arises, What becomes of the extra one of xanthic acid? I had discovered that it was necessary to wash the copper compound with alcohol in order to remove some substance which volatilized slowly and imperfectly on the water bath, and was not soluble in water, in ammonia, nor in solution of potassa (aqueous), but dissolved in alcohol and was precipitated by dilution, after the manner of oils. This was the key to the problem.

If the copper precipitate, washed with cold water only, be dried with gentle heat, then steeped for a few minutes in alcohol and thrown on a filter, a yellow solution is obtained, which on dilution with water becomes a milk-white emulsion which does not settle in any reasonable time nor form drops when settled, and which passes completely through a filter. If the alcoholic solution be allowed to evaporate spontaneously it leaves oily drops of a yellow color which readily unite. This oily liquid has the smell which characterizes the xanthates; it does not unite directly with potassium hydroxide, but its alcoholic solution forms with that potassium xanthate. Now carbon disulphide would do the latter; it also dissolves in alcohol and forms a milky emulsion on addition of water. But the emulsion of carbon disulphide settles well and soon forms drops; it readily clears by agitation, as pouring from vessel to vessel, or stirring, the disulphide evaporating, and it is doubtful (or rather it is scarcely doubtful) if anything would remain after evaporation of an alcoholic solution of carbon disulphide. The oily liquid mentioned agrees in every observable respect with the xanthic acid obtained by the decomposition of potassium xanthate with hydrochloric acid, as directed by Regnault, that is so far as my observations go, and I have not the slightest doubt that it is xanthic acid. One peculiarity of it is that, although heavier than water, since it sinks when submerged, yet, in washing it, the moment the surface of a drop is uncovered by the water, the drop, or a part of it floats and is with difficulty made to sink again. It is not very volatile though composed of ether and carbon disulphide. Nitric acid, even hot, seems to only partly decompose it, or decomposes it, leaving an oily residue. A portion of it left all night in ammonia was found solid in the morning, though another portion, not so treated remained liquid; it remelted in time after removal of the ammonia.

I conclude that in the precipitation of copper by an alkaline xanthate, two molecules of the precipitant are decomposed for one of the copper salt; that the copper xanthate is a basic salt and that for every molecule of it formed, a molecule of xanthic acid is set free. There is at least one other instance known, perhaps several others, in which a basic salt is formed in presence of an excess of its acid in the free state, yet it is not usual, I believe.

In my book on assaying I have said that the proper color of copper xanthate is mustard yellow. I now find it orange colored. Something of the shade depends on the state of aggregation, and something on the purity of the alcohol used in making the precipitant. It is probable that fuel oil may form a compound similar to a xanthate, and its presence in the alcohol may modify the shade of the product (also its molecular weight).

Silver in ammoniacal solution is precipitated by a soluble xanthate. The reaction is similar to that with nickel, the compound produced containing empirically 46.75 per cent of silver which, allowing for loss in melting and cupelling, is pretty close to theory calling for 47.16 per cent. Silver is also precipitated from its solution as a double hyposulphite.

Lead and bismuth are precipitated by this

reagent, and the precipitates curdle so energetically that they form compact balls, when agitated. I have not ascertained whether the composition agrees with that of copper xanthate or of the nickel compound.

Nickel xanthate dissolves readily in ammonia, less readily in solutions of ammonium salts not in alcohol. Cobalt xanthate is not soluble in ammonia, but dissolves partly in alcohol, forming a green solution and a black residue. The solution is decomposed by water.

All of the heavy metal xanthates which I have examined are readily soluble in solution of potassium cyanide, and more or less so in solution of potassium xanthate. The latter point is important in regard to gravimetric assays with this reagent; great excess of the precipitant must be carefully avoided, the more so as the presence of re-dissolved metal is not indicated by a soluble sulphide. Potassium-xanthate is made by adding carbon disulphide to an alcoholic solution of potassium hydroxide as long as the disulphide dissolves. If the alcohol and disulphide are in great excess of the potassa, a solution of disulphide in alcohol is present, and turbidity is produced by addition of water. The liquid soon clears if agitated. An excess of disulphide remains undissolved at the bottom of the vessel; an excess of alcohol usually does no harm, except that the copper precipitates settle less readily. With "absolute alcohol" and filtering the potassic solution to clear it of potassium-carbonate before adding the disulphide, the solution finally got may be neutral to test paper, but frequently it is slightly alkaline. This is of no importance in the precipitation of an ammoniacal solution of a metal, but must be guarded against when neutral solutions are operated on; even a slight acidity of the metal solution will not always prevent the co-precipitation of oxide with the xanthate, or perhaps an oxyxanthate is formed.

I have found it impossible to precipitate cobalt-xanthate free from zinc, in a faintly acid solution of both, by means of a slightly alkaline solution of potassium-xanthate; even the pressure of acetic acid in great excess, or of other solvents for zinc-xanthate or oxide proved useless, nor is it feasible, short of a complete decomposition of the mixed precipitate, to remove the zinc from the cobalt-xanthate. This piece of knowledge cost me four months' work and a good deal of money when working on my nickel and cobalt assay.

Sodium and calcium form soluble xanthates, and even aluminium, though the latter very slowly. Alcohol, ammonia and carbon disulphide seem to form a volatile ammonium xanthate, having the color and odor of the others, but it cannot be made neutral. In an ammoniacal solution of copper, the ammonium xanthate produces a brown precipitate which soon blackens. In my one experiment with this reagent I found no free xanthic acid in the copper precipitate which nevertheless seems to be a xanthate, having the characteristic odor, especially when calcined, and containing about 33 per cent of copper. The absence of free xanthic acid in the product may have been owing to an excess of alcohol in the precipitant, which kept it in solution.

NOTE.—In the preceding article on xanthates, the types make me say that the electrolytic process is as accurate as, or, in certain circumstances, more so than, that by a xanthate, whereas I said the converse of this. The error of the type consists in saying "which is" in place of "while," as written. Also, for "capacity of execution" read "celerity of execution," again for "sulpho-carbonates" read "sulpho-carbovinates." (Regnault.)

The United States and the Debris.

Representative McKenna has secured the adoption of the following amendment to the River and Harbor bill in the House:

Improving the Sacramento and Feather rivers, California—\$40,000 of the money appropriated heretofore for improving said rivers that may remain unexpended at the end of the fiscal year, for snagging and dredging operations, and for the cost of the proceedings hereafter authorized, the balance of said unexpended money not to be used until the Secretary of War shall be satisfied that hydraulic mining has ceased on said rivers and their tributaries. If he be not so satisfied he shall institute such legal proceedings as may be necessary to prevent the washing, sluicing, damming or discharging detritus, debris or slickens caused by or arising from hydraulic mining into either of said rivers or any of their tributaries, or into the San Joaquin river or any of its tributaries, or to such place from which such detritus, debris or slickens may be liable to be washed by storms or floods into either of said rivers or said tributaries; and he is authorized to use each part of said \$40,000 as may be necessary for said purpose.

LUMBER INTERESTS AT TRUCKEE.—Messrs. Sisson, Crocker & Co. have sold their entire business interests in Truckee to the Truckee Lumber Co. The only exception in the sale being a tract of timber land owned by them, and which will likely be transferred to another mill owner very soon. Mr. Van Arsdale will remain for the present and superintend the affairs of the concern; whether he will remain permanently has not yet been decided. It will be regretted that Sisson, Crocker & Co. have closed their business relations with Truckee, but the purchasers are well known as being live and stirring business men, and it is certain nothing detrimental to Truckee and her business interests will suffer from the change.—*Truckee Republican*.

California Asphaltum.

A Growing Business in Native Asphalt.

A Los Angeles *Express* reporter recently visited the new factory of the Mineral Rock Asphalt Company, and was shown its operations by C. W. Duffy, the superintendent. The building is a wooden frame, 110 feet long by 60 feet wide, and has a driveway the entire length and a storage capacity for 1000 tons of asphalt. There are four brick furnaces for refining the native asphalt. Each furnace has a present capacity of one ton per day, with a possible increase to two tons. There is also a still for the purpose of distilling asphalt oils. The distilled oil is used to mix with the asphalt in the process of refinement, and the residuum is used for burning. The still is arranged for 15 barrels of oil per day from the Puente wells. Besides these brick furnaces there are portable iron furnaces for melting the asphalt on the streets preparatory to laying it down. Mr. Duffy calls them the "smokeless furnaces," and claims them especially as his own invention. An ordinary oil burner is used in each of the portable, smokeless furnaces, which consist of an ordinary sheet-iron cylinder, three feet high and three feet in diameter, with a cone-shaped bottom, apex downward, with a peculiar-shaped opening at the bottom for the introduction of the oil burner. The cauldron is set in above the cone. These smokeless furnaces do away with all the disagreeable odor which is so obnoxious to passersby, when hrea or asphalt are being melted in the usual way.

The Supply.

The asphalt had from which the company gets its supply is near Anaheim, and Mr. Duffy says the company has enough to plaster all Los Angeles county a foot thick, and then have enough surplus to supply all orders from other points. He claims they have millions of tons of it. The supply of asphalt in the world is rather limited. In the East the market is controlled by a monopoly, the Barber company, which has leased the island of Trinidad for 99 years from the English Government, and will not sell to anybody unless it is for pipe-dipping purposes.

Its refinery is at New Orleans. In the minds of the uninformed, hrea and asphalt are considered the same, but Mr. Duffy says they are not so. He showed the reporter specimens of the two, which certainly show a difference. Brea is fully 100 per cent lighter in weight than asphalt, and lacks the consistence of the latter. Mr. Duffy defines hrea as a paraffine deposit, while asphalt is more of a limestone or bituminous rock heavily impregnated with oil. He handed the reporter a specimen of limestone composed almost wholly of sea shells, and said the asphalt comes from them.

The Process of Refining.

Like everything else, is simple enough when understood. The brick furnaces in the factory are all heated by oil burners, especially adapted to them by Mr. Duffy. The native asphalt is put in them and is first treated without oil. After it reaches a certain point that is known by the experienced operator, a proportion of oil is added sufficient to turn it down to a proper consistency for use. It is then drawn off in a liquid form into a bed, and allowed to cool, and is then broken into blocks for shipping. On the street, these blocks of refined asphalt are put into the smokeless furnaces, and different proportions of palzalina, limestone and silica are added, according to the different purposes. This composition is melted and poured out on a concrete foundation in blocks, squares, and other designs. The concrete is composed of Portland cement and gravel, in the usual proportions, from three to six inches thick. The cement foundation is allowed to thoroughly crystallize, after which two and a half inches of the composition of asphalt, limestone and sand, mixed in the proper proportions, are spread over it, and tamped and rolled. Such a pavement on the street will stand the heaviest trucking that any city has. The iron shoes of the horses will not slip, as there is sufficient sand in the asphalt to form a grit. The asphalt does not shrink or crack like brea, but becomes more compact with age. High and low temperature does not affect it. It does not soften in the summer heat nor harden with the winter cold.

Asphalt will also be used for roofing. A layer of asphalt three-sixteenths of an inch thick, on a burlap foundation, can be rolled up like carpet. Nails driven through it do not cause leaks, because the asphalt cloeees tightly around the nail. The danger of fire is no greater than with other roofs, because the asphalt disintegrates under heat rather than burns. The other uses for asphalt are sewer, water and drainage pipes, cellar floors, reservoirs, etc.

The Cost

Varies according to the foundation and thickness of the asphalt. As a general rule asphalt pavements will cost twenty-five per cent less than any other pavement that can be laid down in Los Angeles. About fifteen cents per square foot for sidewalks, and twenty-five cents for streets is a fair price. The roofing will cost about two and a half cents per square foot. The cost of the pavement in the East is 40 cents per square foot.

Just Starting.

The company is just starting in business. About thirty men will be employed in the

factory besides the street men, the miners, officers and agents. The company has incorporated with \$25,000 capital stock, with William Lacy, president, Walter S. Maxwell, secretary, and C. W. Duffy, superintendent. It is their intention to establish agencies East and elsewhere to sell their refined asphalt. The company has a contract with the city to pave one hundred and twenty feet of Spring street, north of Second street, in front of the city hall lot, and twenty-five feet to the center of the street. Work will be commenced on the contract next Monday. The sidewalk on this same front will be widened to fourteen feet, and also paved with asphalt.

No New Thing.

Asphalt pavements are not new. Mr. Duffy laid 100,000 square feet between this post-office and custom house, San Francisco, ten months ago, that is in a better condition now than when laid, because it is more compact. He also laid some for J. J. Haley, the real estate agent of the Southern Pacific company. Washington City has sixteen miles of asphalt pavement. Chicago has six miles; Omaha, eight; St. Louis, six, and so on. It is used largely in Europe. The monopoly of the Barber Company has prevented its general introduction in the East.

Hawthorne District.

Hawthorne mining district, situated twelve miles in a southeasterly direction from the town of Hawthorne, the county seat of Esmeralda county, Nev., continues to create some stir among mining experts. The road from town is a comparatively good one. Nine miles from Hawthorne the road enters a "wash" which runs between two chains of mountains for a distance of eighteen miles, to Garfield. (Farrington Bros' mines and mill.) About two miles from the mouth of the "wash," on the right hand side on the top of a small hill, is the Pamlico mine. This ledge is small, but exceedingly rich, assays obtained going as high as \$4,800 in gold. On the same side and half a mile further on, we encounter the high hill with the Nevada, Ohio, Antony, Mountain King and Keating claims. They are all well-developed. The Nevada has a very well-defined ledge running in a tunnel at a distance of 128 feet and down an incline of thirty feet. The average width is four feet and the average assay \$45. The Ohio, Mountain King and Antony have defined ledges. Next in order comes the Detective, New York, Red Bank and Golden Nugget, all well defined. The Red Bank has a shaft 100 feet deep; the ledge is small, but rich.

At a point three miles from the mouth of the wash (Lake City) the road branches off to Lapanta, a distance of one mile. The Lapanta is situated on the side of a limestone hill that has a black dike (dolorite) running the whole length of the hill. This mine is worked entirely through tunnels and inclines, all connecting with each other, and are fully one-eighth of a mile long from a certain point to the end of the deepest point, a perpendicular depth of 100 feet. The ore is free gold, and exceedingly rich. Twenty-two men are underground, and the stoves increase in size daily. The Lapanta Company own the surrounding claims, viz., the Esmeralda, Alabama, Golden Bullet and Golden Gate. The Esmeralda is the only one developed; it has a shaft 80 feet, with a drift 35 feet long. Ledge matter was encountered, and the work was postponed until the developments in the Lapanta exposed mineral in the Esmeralda. One-quarter of a mile east in a direct line is the Dictator Consolidated. The Mountain Chief and Dictator, adjoining claims, were consolidated and incorporated March 20, 1886, with 100,000 shares. A working capital of 15,000 shares were set aside at 25 cents to be used for developing the property. Five men are here at work. The main shaft is 78 feet deep; the ledge at the top is three feet in width, has increased to ten feet at the present depth. The general average of the whole ledge is \$22 in gold. About \$5000 has been expended in developing this claim, and ore has been encountered in seven different tunnels and shafts. North of the Dictator is the Narrow-gauge, Unknown and several claims owned by J. Moss. West of these are the Deposit, Mayflower, Lapanta Nos. 2 and 3. South of the Dictator is the North Star Consolidated, incorporated recently and including three gold claims. East of this is the Sagebrush, Elsie, May and Norton claims. There are hundreds of monuments all over the country, and everyone has a claim. All that is needed is a mill, and steps are being taken for its construction. Water can be obtained by sinking, and the district will soon prove to be better than was ever claimed for it.—*Reno Gazette*.

C. E. ANTHONY a mining man well-known throughout Grant county, has made the final payment of \$40,000 all told upon the Anderson mine and extensions in the Apache district, N. M. These properties are producing now eight cars of \$100 per ton ore a month, and Mr. Anthony informs a representative of the *Silver City Enterprise* that there is no limit to the shipping ore at present exposed and ready to break in this magnificent property. The ore is a splendid fluxing material and is much sought after by the competing smelters.

Running Tunnels for Quartz.

Tunnels for mining purposes have never been especially successful in Colorado, though they have been frequently constructed, and have been favorite methods of development among the myriads of fresh mining superintendents, or managers as they are called now-a-days, who have cursed this industry in this State. A mania to run a tunnel seems to possess the tenderfeet who dabble in mining and they generally start one, with disastrous results to the treasury of the company which foots the bills. The tenderfoot miner never learns anything from the experience of others. He is an admirable specimen of the genus fool, to which we mostly belong. He is an illustration of the oft told truth that few men will learn from the experience of others.

There is scarcely a mining county in the State which does not have many of these dark and deserted tunnels as illustrations of folly. Some of them cost hundreds of thousands of dollars, and were run to develop a prospect whose value was an unknown quantity, and evidenced only by one or two prospect holes on the surface.

Tunneling is the most costly method of development known, under ordinary circumstances. The only good reasons which ever exist for running them, as recognized by mining engineers and experienced, intelligent miners, are three:

First—Where the cost of hoisting water is sufficient to make it profitable to run a tunnel for drainage purposes.

Second—Where the mine is located in a practically inaccessible spot, or where danger from snowslides renders developments on the surface of the mine dangerous.

Third—Where the object is to feather one's nest by selling stock, leaving the purchasers to "hold the bag." The last reason may not be generally recognized as a worthy one, but as the great majority of men evidently appear to recognize stock swindles as a legitimate line of industry, it must be classed among the valid reasons for running tunnels.

Excepting a few in the San Juan country which are run for the second reason mentioned, and less than half a dozen in Northern Colorado, not one can be called to mind which ever had any sensible and honest reason for existing. Still this method of development is going on with its usual vigor.

Time may come and time may go,
But folly runs on forever.

As all moneys expended in mining and prospecting are chargeable to the mining industry, it is no wonder that the saying is common that "every dollar produced in mining costs two dollars." The only wonder is that it don't cost a good deal more than two dollars.—*Denver Tribune-Republican.*

Mining in Nevada.

The *Genoa Courier* says: A revolution has taken place in the management of mining affairs as well as other industries in Nevada. In years past when farmers sold their half-cured hay in the field at \$100 per ton, and the price of everything else was in proportion, money was plentiful and speculation and extravagance was a natural consequence. Mines were operated on assessments and the owners made their money out of manipulation of the stock. Superintendents were chosen from a class of men who were good for nothing else, and this was generally the only qualification they possessed. Extravagant salaries were paid, and waste, mismanagement and dishonesty prevailed in every quarter. Eastern people were victimized to such an extent that it has ever since been a difficult task to convince them that there is any such thing as legitimate mining. However, those days of hurrah and excitement have passed, and we may say that mining is now established on a solid business basis. Men are selected to superintend the work who have a reputation for experience and ability. Economy is practiced in all the details, and while the annual product of precious metals may not be as great as in times past, yet we predict that the average profit will be much greater on the capital invested. Experience is a thorough teacher, and when Nevada shall have learned her lesson perfectly and when her people give up gambling and turn their minds to legitimate mining, they will prosper. There is no lack of gold and silver in Nevada, which, by the use of capital, intelligence and economy, can and will be mined at a profit; but fortunes can no longer be made and lost in a day in mining speculations.

BULLYCHOOP DISTRICT.—Bullychoop mining district is now alive with business activity. H. B. Williamson is at work putting up his mill, some of the machinery of which is not yet on the ground. The owners of the Pound Ciske are developing their mine rapidly and taking out rich ore. One of the partners has gone to Frisco to see about purchasing a mill and concentrators. Phalen & Parker, who boned the Caucasian mine, are running a tunnel to tap the ledge about 185 feet deep. The vein is about three feet wide, and the ore extracted from a 35 foot shaft milled \$50 a ton. On the first of May the Bullychoop company expect

to resume developments. Their hoisting works are now at Anderson. The Bullychoop road is to be extended to Indian creek this spring, which will open a good wagon road from Anderson to Weaverlyville. The miners of this camp have petitioned for a postoffice, and have also asked the Postal Department to establish a mail route to connect with the route to Ono. Stevens & Smith have commenced work on their hotel, and J. S. Finch is building a residence.—*Shasta Co. Democrat.*

ACCIDENTS IN MINES.—The Royal Commission appointed to inquire into accidents in metalliferous and other mines have issued their final report. In the course of their report the commissioners say:—The evidence taken by the commissioners had made it clear that one important factor of protection against falls of roofs and sides was to provide the miner with a good light, convenient and handy, which would enable him, whilst engaged in getting coal or other mineral, to see and protect himself against defects in the sides and roof of the working places. Whilst we think that the safety hooks at present available may have contributed to prevent fatalities from over-winding, we believe that the best appliance for the purpose is an automatic steam break attached to the winding gear, and we think it desirable that such brake should be introduced where practicable. We consider that measures should be adopted to deal more systematically, and, if possible, more expeditiously, with casualties resulting from the various sources of accidents dealt with in this report. Collieries or mines should be required to provide an ambulance and stretchers for the purpose of conveying to their homes sufferers from injuries received while in the discharge of their duties. Arrangements should be made for the establishment of centers in mining districts, where additional appliances for succor and relief, and also special appliances for exploring purposes, should be maintained in an efficient condition, so as to be ready for use at the shortest notice. It is most desirable that facilities should be afforded for the instruction of men in the use of special auxiliary appliances for exploring purposes, and in simple measures connected with the provisional treatment of injuries. We attach great importance to the systematic inspection of each mine by the workmen, as provided for in General Rule 30 of the Coal Mines Regulation Act, 1872, and we recommend that this provision should be generally and regularly acted upon.

ANOTHER GOLD SAVER.—Edward Pike, of Salt Lake, is in Central, Col., with a sluice-hox amalgamator which commends itself as being ahead of anything in its line in present use. The invention consists of a series of fixed hoxes set about six feet apart in a main sluice. These fixed hoxes are made about two feet long, and at the upper end they join the bottom of the main sluice again, making a triangular shaped hox. At the bottom of this is placed the quicksilver or amalgamated plate, and above, running parallel with it, and covering the entire fixed hox is a plate perforated nearly to the end. In working, everything is minutely divided and thrown with force through the perforated plate upon the working plate below and is then again worked up into the main sluice. Sureness of contact with quicksilver—no matter how fine the mineral may be—is simply accomplished, while there is no danger of "filling up" from heavy sand or gangue. An application of electricity is also made in this hox which has never been successful before, by which the lower and the upper plates form the negative and positive poles. This is claimed to keep the quicksilver bright and catching, and can readily be attached. Simplicity, cheapness of construction, general adaptability and efficiency—numerous tests having proved its superiority—are what is claimed for this machine. A rough test at one of the mills in Central, showed traces of amalgam in a couple of hours. Mr. Pike will place one or two machines in Colorado, then come to Idaho to test it on Snake river float gold.

CONSERVATIVE MANAGEMENT.—From a London mining paper we learn that quite an exciting meeting of the shareholders of the Ruby-Dunderberg Company was held in that city recently. By some of them it was considered that the allowance made the triphiters in the mines was too liberal. We have not heard of any of said triphiters having become possessed of a competence, even after years' of hard labor by some of them. In fact, we know of none of them who can boast of a bank account. A brief visit to the Base range would, without doubt, convince any of said dissatisfied shareholders that the Ruby-Dunderberg's management here is one of the most economical, reliable and conservative in the district.—*Eureka Sentinel.*

SQUAW CREEK.—All the mines being opened on Squaw creek are looking better every day. The L. M. Co.'s mill has been doing splendid work turning out hullion at a rate exceeding the company's anticipation. Finding that they were wasting too much in the sulphurets the mill was stopped till concentrators and another mill is added, which have already been ordered. The Cistus mill is doing good work and this company's clean-ups far exceeded their expectations also, and as a consequence members of the company wear broad smiles. We hear it reported that Jack Conant has ordered a mill which he will erect on the Uncle Sam.—*Shasta Co. Democrat.*

The Public Lands.

It looks very much as though 1886 would prove a bad year for those who are holding public lands without due right thereto. Congress is making short work with forfeited land grants which will restore a vast area to this public domain, and General Sparks, the commissioner of the land office, is laying up much trouble for individual intruders who have obtained possession of lands without proper title. It rather seems now that it was high time a new broom was introduced into the Government land office and General Sparks has handled it vigorously. He was called upon by the Senate last week to report the number of special agents he had employed and their duties, and the extent of evil he suspects may be gained from his answer to the Senate, which was that if the increased force recommended in his annual report he granted, the entries suspended by his order of April 3, 1885, will be investigated and disposed of in about a year and a half. A large percentage of these entries, he thinks, are fraudulent. The proportion of new cases that will require such investigation will be much less than in those previous to April 3, 1885, since the order of suspension has had the effect of materially checking the making or completion of fraudulent entries. It was the esse with which frauds could be perpetrated under existing laws and the immunity offered by the hasty issue of patents, he says, that encouraged the making of fictitious and fraudulent entries. The certainty of a thorough investigation would restrain such practices.

Commissioner Sparks believes, however, that the evil cannot be fully cured without repealing all the laws under which the plundering system has prevailed: to wit, the pre-emption, homestead, timber culture, timber land and desert land laws, and says the questions, broadly stated, are whether the public lands shall be protected and an honest acquisition of title thereto insisted upon or the dishonest appropriation thereof be allowed. The questions cannot long remain in abeyance. With the present heedless rush of speculation and monopoly, the public domain will be absorbed in a period of time so brief that even preventive measures against fraud and misappropriation may soon be too late to save any considerable portion of the public lands for homes for the people.

It seems that the demand for land from actual settlers cannot be filled much longer until the land illegally held be restored to the public domain. There seems to be now more than ever a demand for such farming lands, for our growing population needs more room. This being the case, it is much more important that all land which is fitted to maintain families on small farms should be restored and used as it is the manifest intention of the people that it shall be used.

At the railroad shops in Sacramento there are now 1200 men at work, the employees having been recently increased to that number. The additions to the force have been made gradually, and have been found necessary by the constant accumulation of work. The outlook for continued employment of the car-shop employees was never brighter. The railroad rolling shop is running night and day, turning out "track trimmings" for the extension of different lines. There are about 50 flat and hox cars to be rebuilt and 125 "flats" to be transformed into coal cars. The street cars for the new Hayes Valley cable line are being manufactured at these works, and there is a large number of small jobs on hand.

IONE COAL is being substituted for wood as fuel at the Jackson gas works. Mixed with coke, it is found to answer admirably. It costs \$5.50 per ton delivered at the works—the same price as a cord of wood. It is claimed that a ton of coal will last twice as long as a cord of wood, and if this is found any way near the truth, wood will be entirely dispensed with. Jackson is only 14 miles from the coal mine, and yet it costs nearly double to get coal here than it does at Fresno—200 miles distant, where the same coal is sold at \$3 per ton. Such is the effect of railroad communication.—*Amador Ledger.*

The question as to whether a corporation has the same rights as an individual, under the law, in locating mining claims is about to be tested. A Colorado court recently decided that a mining claim could not be located in the name of a corporation, and an appeal to the Supreme Court of the United States has been made.

A **POCKET** was recently found by a man named Kipp, near Jayhawk, in this county, which panned out 22 ounces of gold. The queer part of the story is that he was led to its discovery by an old lady who dreamed that the gold was there, and who directed him where to look for it.—*El Dorado Republican.*

The *Mariposa Gazette* says: We understand that the branch railroad from Turlock to Merced Falls will be built, the money required having been raised, and work will soon be commenced.

MOTH INFESTED articles should be saturated in naphtha or benzine. It injures nothing and kills the destroyer.

Notices of Recent Patents.

Among the patents recently obtained through Dswey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

DISINFECTANT.—A. P. Bouton, assignor of one half to W. B. Farwell, S. F. No. 341,091. Dated May 4, 1886. This is a composition of several ingredients which is odorless and harmless, and the action of which is instantaneous. It is applied by sprinkling, pouring or exposing in open plates or vessels, or using it in any way in which disinfectants are now used.

COPYING PRESS.—David Samuels and L. Breidenstein, S. F. No. 341,056. Dated May 4, 1886. The invention relates to that class of copying or letter presses in which a roll or rollers are employed to effect the necessary and equal pressure upon the copying hook which passes under or between them. It is so arranged that the pressure is a constant one and is regulated in force according to the thickness of the letter-book. It needs no adjustment, this being entirely automatic.

AUTOMATICALLY FEEDING WINE CASKS IN CELLARS.—Geo. Johnston, S. F. No. 340,786. Dated April 27, 1886. The object of the device is to keep constantly full the casks or vats of wine or other fermented liquors, thereby lessening the risk of acetic fermentation or other deterioration by exposure to the atmosphere. The invention consists of a novel pipe service for the casks or vats and an elevated supply or feed tank, connected with said service, said tank being actuated by a series of weights to rise as its contents are discharged, whereby the level of the liquid remains at the same elevation above the casks or vats and maintains the same pressure thereon.

ANKLE AND SHIN BOOT AND CORD PROTECTOR FOR HORSES.—John A. McKerron, S. F. No. 341,032. Dated May 4, 1886. This is a boot for horses for protecting the ankle and shin and also the cords in the rear part of the leg. It consists of sections pivoted or hinged together, so as to work independently on each other, these sections having elastic straps attached to them, other sections having huckles secured to them to make the fastenings, these sections being padded and united with the first-named section by pads or rolls, which extend horizontally between the two, passing around the rear portion of the leg.

MACHINE FOR MAKING PICTURE MOLDINGS.—Samuel E. Perry, S. F. No. 341,049. Dated May 4, 1886. This machine for making picture moldings is one of that class in which a pattern-roller and an underlying feed-roller are rotated in opposite directions, and the plastic material is passed between them. This invention consists in the novel construction by which the pattern-roller may be readily removed for the substitution of another with a different pattern, in the arrangement of power-transmitting gears between the two rollers, which permit the vertical adjustment of the pattern roller, still preserving their engagements or mesh, and in the general construction of the machine.

AIR-COMPRESSOR.—Geo. E. Dow, S. F. No. 341,099. Dated May 4, 1886. The invention relates to certain improvements in compressors for air or gas, and is particularly applicable to that class in which the medium is compressed in two or more stages by means of receiving and delivery cylinders, in each of which the compression is partially performed. It consists of compressing-cylinders having their axes in the same line, and the pistons connected with piston rod in such a manner as to be actuated simultaneously, so that no stuffing boxes are exposed to the heat arising from final compression. It also consists in an improved means for surface cooling and in certain details of construction.

GRAFTING IMPLEMENTS.—Orville H. Congar, Pasadena, Nos. 340,699 and 340,700. Dated April 27, 1886. These patents relate to a mechanical device for grafting which has been quite widely tested in this State this season and has met with much favor. The device belongs to that class of grafting implements which are designed for properly preparing the stock for that intimate bark union with the scion, which is necessary for the complete success of the operation. It consists of a stock or handle carrying a peculiarly adjustable and self-discharging, approximately U-shaped or angular knife, adapted to penetrate the edge of the stock, and in a swinging hammer-head attached to the stock and carrying a blade or chisel, adapted to make a cut in the side of the stock at right angles to the U-shaped knife and immediately below it, whereby a core is cut out, the removal of which leaves a mortise for the reception of the scion, which is properly prepared by means of a tool which is covered by the second patent mentioned above and which consists in parallel adjustable knives adapted to receive the end of the scion and between them and cut or shave off from each side sufficient material for a tenon. By the joint work of these two devices a scion is set in the stock with mechanical accuracy as a joiner's tenon in a mortise, and perfect contact of the materials of the two is secured at all points. Aside from the facility and speed with which the work is done, there is decided advantage in the exact fit secured and in doing away with splitting the stock—both of which features of the device administer to strong and healthy union.

Passing Events.

Silver miners will feel discouraged to see the low quotations of silver this week, the price having reached 98 cents per ounce—the lowest in 125 years. This will have a very bad effect on the silver mining industry.

The Anti-Riparian Convention is in session in this city this week. The recent decision of the Supreme Court of this State, which enforces the old English law of riparian rights, will, it is thought, do great harm to the regions of the State where irrigation is carried on, and where water is taken from streams for mining ditches. The miners, as well as the farmers, are interested in the question.

Honduras and Alaska are just now attracting considerable attention from the reports received concerning gold fields. There are drawbacks to both regions, however.

XANTHATES.—Since the printing of the "first forms" of this week's PRESS, containing Mr. Aaron's article on xanthates, we have received a letter from him asking us to return the manuscript for correction, as some errors had been made in the modus of the reaction in precipitation of copper. However, as the article was already printed, this wish could not be complied with, but Mr. Aaron will make the necessary corrections in a future number of the PRESS.

Tributing.

The Dunderberg mine, at Prospect Mountain, Eureka, Nevada, one of those belonging to the Ruby and Dunderberg Mining Company, of London, has been worked entirely on the tribute system for the past year. The results to the company, however, have been less than for some time past, owing to a smaller number of men working there and the quality of the ore being generally of lower grade. Only 419 tons were extracted, from which the company realized but \$1889.

At the recent meeting in London some of the shareholders were opposed to the tribute system, as they thought it was only adopted when owners think poorly of a mine, or when the funds are not forthcoming for the company to work it themselves. The secretary replied to certain questions on the subject by saying that the company did not make arrangements with one man for the whole of the tribute, but get them to go to work for themselves. They work in gangs of two and three. At present, the mining camp being in low water, many of the best miners have left it altogether, and it has been difficult to get a sufficient number of tributers. Each arrangement is a separate one with the mining captain. As a rule, we get one-fourth or one-fifth of the proceeds; they pay all expenses to the mill. The tributers will not do dead work; they only follow ore. They got from the Lord Byron mine, belonging to the company, three times as much as the company itself, but they have to pay wages and smelting, the owners getting then one-fourth without expenses.

One of the shareholders declared that it was always dangerous to put mines on tribute, and he particularly objected to the system at Eureka, where the wages are not too high. Another thought that the directors had done right in working by tribute. He doubted, considering the rate of wages, whether the company could get as much by working the mine by day's work as in working it by tribute.

One of the directors said the shareholders seemed to forget that they could get rid of the tributers at a month's notice, but the board were guided by the mining captain. The manager said he wished to employ them because they were producing better results by working on tribute than by working in the ordinary course. If he came upon a body of ore he would at once stop the tribute, but in the meantime the tribute was so much profit. However, this matter would be discussed again fully at the board. The shareholders must leave the directors a little discretion, but in the meantime it was undeniable that the tribute had produced a certain amount of money which had assisted the company.

New Fuse and Igniter.

A patent has recently been taken for a new instantaneous fuse and igniter, the object of which is the firing of several holes simultaneously. This firing has hitherto been accomplished by means of electricity, but this is entirely dispensed with when using the new fuse.

The igniter is a tin cylinder from which protrude, like the arms of an octopus, small lengths of a special kind of fuse which burn instantaneously. A piece of this fuse is inserted into each hole intended to be fired, a piece of ordinary fuse serving to convey fire to the igniter.

After lighting the ordinary fuse, the miners have plenty of time in which to retire. When the fire reaches the igniter, it flashes down in an instant to each of the separate charges, and they explode simultaneously, doing more work than if they had been exploded singly.

TRAVELING CORRESPONDENT. — Frank W. Smith leaves this week for a trip to Washington Territory, British Columbia and other northern districts, in the interests of the MINING AND SCIENTIFIC PRESS. Mr. Smith has previously represented the PRESS in the mining regions, having once traveled through New Mexico and Arizona. His letters from the various mining camps were full of value for our readers. He has had considerable experience in mining districts, and we trust that those he meets in his travels will favor him with such information as they possess concerning the regions where they reside.

New Drilling Machine.

John C. Muirhead of Grub Gulch, Fresno county, has obtained a patent through the MINING AND SCIENTIFIC PRESS agency for a form of rock drill, which is a sort of combination of hand and machine drill. The blows are struck by the miner with a hammer on the rear end of the drill, and the rotation is made by a foot-treadle. A standard is used just as in a machine drill, so that the implement may be fixed in any position in a shaft or tunnel. On the standard is clamped a plate or frame from which the drill is supported. The ratchet and its journals are fixed to the plate and are made hollow, being shaped to fit the exterior of the drill which is of polygonal steel. The ratchet and journals are made in two halves, so they can be thrown back to allow the drill to be put in its place. The drill can be put in the device without trouble, and the expansion of the drill point or the battering up of the head by the blows upon it will not interfere with the drill being introduced or taken out.

In order to rotate the drill and ratchet, a movable pawl is fitted to slide on a guide and a spring is fitted fixedly within this guide box and tends to force the pawl upward, so that the projecting end or hook will engage a tooth of the ratchet wherever it has been raised above the tooth. This pawl is connected by a cord or rod attached to a foot pedal, so the drill may be rotated while being operated. The drill may be fixed at any desired angle.

When the miner desires to work with this drill, he strikes upon the end of it, the point resting against the rock in line with the direction in which it is desired to make a drill hole. As he strikes, he presses his foot upon the treadle and thus rotates the drill slightly an instant before the blow falls upon the head of it. In this manner a man can easily do rapid drilling work. The mechanism is quite simple but appears to be effective.

Bar Silver.

The latest quotation for bar silver, in New York, is 98 cents per ounce, the lowest price ever reached. A week or so ago, when it fell below \$1.01, the silver miners felt discouraged, but now there is a much greater fall. There are many mines that can no longer be worked to a profit with such a very heavy discount on the product. When silver is supposed to be worth \$1.29 an ounce, and only sells for 98 cents, with no certainty of its remaining even at that figure, silver miners may well feel discouraged. With lead and copper at low figures also, men who are mining either of these three metals must have very good ore and plenty of it to make any money. There was a sharp decline in silver some ten years ago, but it was only temporary, but that prevailing now has been so gradual and steady that there is no hope of a sudden upward jump.

There is a strong probability that this marked decline will close down a number of mines that have been just keeping even at former prices. It is only a year since that silver was \$1.10, and now we have it at 98 cents. On the 17th inst., the price in London was 44½ per ounce 925 fine, or 98 cents in New York per ounce 1000 fine. This makes the value of a 41½-grain dollar 75.9 cents. It costs the Government about 1½ cents to make one of these coins. A standard dollar made from bullion bought at the 98 cents valuation costs the Government 77.4 cents. These coins are used to discharge obligations of 100 cents against the Government. Under free coinage this profit would go to the owners of the bullion.

There have not been many fluctuations in price this year, the quotations showing very little change until about the first of April, since which time the decline has been steady. The prices are really fixed in London. The changes cabled from London to the Bulletin since March 4th of this year show the ruling prices on the dates mentioned, and have been as follows:

Coal Consumption on Steamships.

The owners of some of the "greyhounds of the sea," running as passenger steamers on the Atlantic, are seriously in doubt as to whether the very large end fast steamers have done them any good. To make the high speed which they must to maintain reputation and attract tourist travel, entails great expense for fuel, and it is only for a few months at a time that these steamers make any profit. In fact they must have a full complement of passengers at any time to pay. They save a day or two days' time in crossing the ocean, but at the sacrifice of much money. The first cost of these fast steamers is very great. Their engines must be of superior make and the extensive machinery and boilers and necessary coal bunkers take up a great deal of cargo space. On a single trip the *City of Rome* is said to consume no less than 2300 tons of coal.

Since the loss of the *Oregon* many timid travelers are of the opinion that it is better to go with less speed and more safety. Judging from present appearances, the expensive and fast steamships are not likely to increase in number as rapidly as heretofore. Some of the companies which have built them have had to give them up for slower and less expensive vessels. Every effort is, however, now directed toward reducing coal consumption, and triple-expansion engines are displacing the compound. It will be remembered that part of the price paid by the Cunard Company for the *Umbria* and the *Etruria* was made up of the two steamers *Parthia* and *Batavia*, which are now the property of Mr. Pierce, M. P., president of the Fairfield Company. The old compound engines were removed by him to make room for triple-expansion engines and steel boilers. The log of the *Parthia* in 1883 shows that she burnt 47 tons of coal per day of 24 hours when going at a speed of 11 knots. Her log during 1885-86 shows that the consumption was 25 tons at the same speed. Her speed is now much higher, but the comparison must necessarily be made with her old rate. The *Batavia* gives still better results. The consumption in 1883 was 40 tons per day at 11 knots. In 1885, with the new engines, it was only 21 tons.

Domestic Industries.

The prevalence of low freight rates for some months back, between here and the Eastern States, has not been to the advantage of our home industries, many of which have suffered from sharp competition. At the last meeting of the Manufacturers' Association the depression of the manufacturing interests was considered and various suggestions were offered how best to improve them. It was decided to procure detailed information of the actual cost of production and expense of leading articles at the East for comparison with like articles here, with a view of showing the benefit of patronizing domestic industries, and so giving employment to more of our own people.

The question of freights to and from the Pacific coast, and particularly in relation to the distribution of goods from this city to local and other points, was discussed at length. It had been found that a great diversity of rates exists in different directions, and to many places the cost of transportation entirely prohibited the supply being shipped from San Francisco. It was accordingly resolved to appoint a committee of the board to act in conjunction with like committees from the Board of Trade and Chamber of Commerce, with a view of procuring an adjustment upon some equal and uniform basis of the rates of freight on goods coming to or going from the coast, and particularly upon goods going from San Francisco to interior points.

After considerable discussion, and in view of the good the association has already accomplished and the greater benefit to be secured, by united and intelligent action toward the preservation and advancement of these interests in this State, it was proposed that a committee should be appointed to devise and present a plan for obtaining the active cooperation of all engaged in domestic enterprises, so that the common interests may be upheld and the association be, in fact, what its name indicates—an exponent and promoter of every industrial pursuit, which gives employment to our citizens.

It is believed in Washington that the President will veto the River and Harbor bill,

The Frisbee-Lucop Quartz Mill.

(Continued from page 337.)

bolts. Between the roller and disk plate a thin piece of iron is shown, which takes the wear of end of roller, and is replaced when worn out.

These mills are built in three sizes, 24-inch, 20-inch and 10-inch, these sizes being the inner diameter of the ring. The weight of this 24-inch mill is about 5500 pounds. The inner diameter of the ring is 24 inches, and width of face of ring six inches; the rollers eight inches diameter by six inches face, weighing 80 pounds each. The main shaft is of steel, three inches in diameter, with bearings 10 inches long and three inches diameter. The speed in running should be 300 revolutions per minute, at which rate the mill will grind 2000 pounds per hour of quartz to 60 mesh powder, and up to 4000 pounds of softer material, requiring from 12 to 18 horse-power, according to hardness of material ground and speed of the mill. The material to be ground is first passed through a crusher to a size of one inch or less, as may be convenient, and then fed by a chute directly on the feed shoe. The screen mill can be used for either dry or wet grinding; and the only change necessary for wet grinding is to introduce the necessary amount of water into the feed opening in the top of the mill. This is a valuable feature, as it removes the necessity for drying rock before grinding, when the pulp is to be worked wet, by concentration or amalgamation, as it can be run directly to concentrators, pans, or plates.

The 20-inch mill weighs about 3800 lbs.; the interior diameter of the ring is 20 inches; width of the face of the roller, 3 inches, and has a capacity of 1000 lbs. of hard quartz per hour to 60 mesh powder dry; speed, 500 revolutions per minute, requiring about 8-horse power.

The 10-inch mill is intended for assay offices and for use where only a small production is required, and has a capacity of 150 to 200 lbs. per hour.

Mr. E. N. Riote, well known on this coast as a skillful metallurgist, and now manager of the New York Metallurgical Works, has been using two sizes of these mills on quartz for five years, and states that they pulverize more quartz for a given amount of wear and tear than any machine he has tried. The 12-inch mill gives 200 to 300 pounds per hour dry, when closed with a No. 40 screen. Ninety per cent of the pulp passes a No. 80. Mr. Riote says: "The pulp is almost identical with that furnished by dry stamp battery, as comparisons show. Wet, 400 pounds per hour can be relied upon, with the same screen, averaging finer than battery pulp under similar circumstances. The main advantage, however, is that the pulp can be discharged as a thick mortar just the right temper for pans. Those who know by experience the great amount of water needed by stamps if they are to do much work, of the trouble in settling tanks, of the floating chloride, etc., etc., will see in this fact the machine's strongest point for free gold and silver ores. The 20-inch machine gives on average gold and silver quartz 800 to 1200 pounds per hour dry (all acid of the pulp from the 12-inch machine applies to the pulp from the 20-inch). One ton an hour up to 2500 pounds is easily achieved, running wet. The change from dry to wet can be made instantly by simply turning on water. Of the 24-inch mill we can only judge by the action of the smaller ones, and confidently believe that one ton an hour, dry, or two tons, wet, of hard quartz would be a low estimate.

"Its first cost and cost of erection, as compared with stamps, is very small, \$800 paying for a machine ready for the belt, equal to a 10-stamp dry mill. In using stamps, dry two-horse power is required to pulverize a ton of good, honest quartz in 24 hours. The 20-inch mill will give from 10 to 15 tons in 24 hours and require eight-horse power. We find the wear of parts and renewals to be less than with stamps, say from one-half to one pound per ton dry, according to the hardness of the quartz, and from one-quarter to one-half pound per ton in wet crushing. In comparing the latter figures it should be borne in mind that wet crushing through a No. 40 wire mesh is meant, not crushing through a No. 2 or No. 3 sloop-punched screen.

Renewal parts are furnished by the company, whose advertisement appears in another column. A 24-inch mill costs complete \$1,200; 20-inch, \$800; 10-inch, \$400. Several of these mills will shortly be put to work on mines in this State, where miners can examine them, and we shall mention the localities in due time. Mr. Gideon Frisbee, the manager of the company, is now in this city arranging for the introduction of the machine on this coast.

A Curious Gold Mine.

There is a gold mine in the Port Curtis district, Queensland, which has some very peculiar characteristics. The gold deposit is supposed to have been formed by a hot spring, and the possibility that the discovery may lead to others of equal importance in a direction where gold has never hitherto been looked for, lends it a wide significance. Given a hot spring rising from depths in which auriferous ledges lie hidden, we may look for a repetition of this phenomena of Mount Morgan. Robert L. Jack, the Government Geologist, in a paper ordered printed by the Legislative Assembly, describes this Mount Morgan gold deposit, and after a careful study of the whole formation comes to the conclusion that nothing but a thermal

Ivor and Mulgrave volcanoes, probably dates from tertiary times, and is contemporaneous with many of the basalts which cover auriferous drifts in Victoria.

In the presence of so much ironstone a precipitant for the gold need not be far to seek. Protoxide of iron was probably present in sufficient quantities to perform this important function, but it may have been aided by tannic acid derived from vegetable matter accumulated in the basin. Several instances of the occurrence of vegetable matter in the basin of hot springs in the Yellowstone region are recorded. Precipitation of the gold by means of tannic acid would accord better with the confinement of the gold to the basin or crater of Mount Morgan (to be afterward alluded to) than precipitation by ferrous oxide.

The outer boundary of the overflow deposit is, in some places, ill-defined, as the "country rock" is frequently impregnated with aluminous, siliceous and ferruginous material, so as to be distinguishable with difficulty from the unmixed deposit. That this deposit does not extend far to the east of Mount Morgan is owing simply to denudation, the deposit having been removed from the steep slope of the hill on that side.

In such active geysers as are accessible to

FIG. 1.—DIAGRAM SHOWING BUILDING-UP OF GEYSER DEPOSITS AND SUBSEQUENT DENUDATION

spring, in the open air, would have deposited the material in which the gold lies. It will be of interest to trace his theory of the subject.

Fig. 2 is a diagram across the valley of the Dee, showing the location of the deposit on Mount Morgan. In class a shows the metamorphic rocks; b, rhyolite, etc., dykes; c, desert sandstone; d, thermal spring deposits of Mount Morgan.

The diagram-section will elucidate the remarks that follow: Standing on the sandstone cliffs, so as to look to the east past the south side of Mount Morgan, the observer can descry across the valley of the Dee the familiar contour of horizontally-bedded sandstone cliffs, stretching north and south. As nearly as can be judged by the eye, they are on the same level as the cliffs on the opposite side of the valley, and there can be no doubt that the valley has been carved out of a

observation, we find a narrow pipe or fissure, terminating upward in a crater-like cup or basin. The Great Island geyser, for example, has a pipe 12 feet in diameter, which has been sounded to a depth of 70 feet. I have seen no satisfactory explanation of the necessity for a cup, nor can I suggest one, but all the same the repeated occurrence of the cup evidently takes place in obedience to some natural law. It may be taken for granted that the Mount Morgan geyser was no exception to the rule, and I believe that the upper portion of the mount, where ironstone predominates, and to which gold is almost confined, represents a basin occasionally filled with a fluid, in which silica, iron, alumina, manganese and gold were held in solution, to be deposited when the bulk of the water from time to time withdrew into the pipe or the subterranean reservoirs with which the pipe communicated.

FIG. 2.—SECTION ACROSS THE VALLEY SHOWING MT. MORGAN.

once continuous cake of horizontal sandstone. The question arises, Was Mount Morgan an island in the sea or lake in which the sandstones are laid down? In that case the hot spring was older than the desert sandstones. The answer is easily made. Had there been shores to this sea or lake where Mount Morgan now stands, the sandstone in the neighborhood would have been full of pebbles of sinter and ironstone derived from the waste of such easily degraded rocks. None of these occur. The hot spring, then, was newer, and not older, than the desert sandstone.

In many places in the North the valleys carved out of the desert sandstone became theaters of volcanic activity. These volcanoes burst out near the heads of the valleys, and filled the lower reaches with flows of basaltic lava, to which we owe some of the richest agricultural land in the colony. Another form of volcanic activity was developed at the same period near the head of the Dee Valley. After the desert sandstone had been uplifted, and the carving out of the present valleys had been carried on for long ages—in fact, till the valleys had nearly acquired their present contours—basaltic lavas flowed down the valleys over the upturned slates of the MacIvor, and over the auriferous drifts of the Mulgrave, and a geyser of enormous proportions spouted fitfully in the valley of the Dee, carrying with it not only water but in all probability chloride of gold.

The Mt. Morgan geyser, as well as the Mac

Working Gold-Bearing Sulphurets.

Concentration and Chlorination in Nevada County, Cal.—No. 2.

(Written for Press by C. A. SCHNECK.)

It is a most interesting and instructive experiment in working a Frue concentrator to turn off the water of the water-spreader for a few minutes. The separation of ore and sand under the latter ceases at once, and a mixed layer of the two materials is carried over the head of the machine; if now the water is turned on again, final concentration commences immediately. The shaking table revolving around the rollers brings continuously forward new portions of settled ore, to be acted upon by the jets of water, and bright yellow bands of clear sulphurets are produced, while the unproductive sand is rolled back.

Quantity of Water in Concentrating.

It must become evident at once from this description that only one quantity of water per minute from the water-spreader will answer the purpose for a certain class of ore, the density of the pulp from the ore-spreader being supposed to remain the same and the traveling speed, number of revolutions of main shaft being also given. Too much water might wash off particles of metallic mineral, and too little would produce unclear concentrates.

But it is not difficult to regulate the quantity of water needed. Changes in the traveling speed and inclination of the table, which latter is at the Providence 3 inches to the 12 feet, are also means to regulate the work of the Frue in producing concentrates of desired purity. The latter expedient

is hardly ever made use of, if the same class of ore is worked. Diminish the uphill travel if too much sand comes over the head, and increase it if the bands of sulphurets are getting elongated under the water-box toward the ore-spreader.

The so-called field between the two latter should always be well covered with diluted pulp in which the final concentration has not yet begun, or, in other words, where the bands of clear sulphurets are not yet to be seen.

Slimes.

The pulp from the Providence battery, passing through a number six punched screen, produces but very little fine slime, and the loss on this account is consequently small; but there is another reason which makes it evident that this loss in sulphurets must be almost nothing. A small percentage of sand in the concentrates is beneficial in roasting them, and the presence of this small percentage, which could be kept out if desired, is a guarantee that all the concentrates are saved, with the exception, perhaps, of the very finest slimes.

In working ore which produces a great deal of fine slime in crushing, concentration becomes more difficult; but even in such a case the Frue will still prove effective, the *modus operandi* being changed to satisfy this class of ore. The effect of the water may first be considered in this connection. If the volume of pulp from the battery plus volume of water from water-spreader is too large, forming a rather thick sheet of diluted pulp on the table, much of the fine slime will wash away and float off, having, under these conditions, not sufficient body, chance and time to settle and cling to the belt, from which it is too far distant—being on top of the supposed thick sheet of pulp. This detrimental effect will be increased if the table is inclined too much. The work to be done in this case, in regard to quality, is therefore a function of the amount of water coming from water-spreader, quantity of pulp from ore-spreader and grade of table; so that, if such ore is worked, most of the fine slime will be saved if the sheet of pulp on the table is thin and the grade small. But the quantity put through in a certain time will be less.

The sub-Treasury at Chicago has commenced packing up \$5,000,000 in silver coin for shipment to Washington, in order to relieve the pressure upon the vaults in the Government building.

Gold to the amount of nearly \$3,000,000 was exported week before last, and foreign houses expect the movement to continue.

MECHANICAL PROGRESS.

Aluminium Iron and Steel.

One of the great difficulties in making castings from steel is to get a product which is solid, sound, homogeneous, or free from blisters or cavities. The addition of ferro-manganese and other compounds containing carbon, silicon and manganese makes the product somewhat more solid, but deteriorates the quality in other respects, as the product gets harder and more brittle or red short. It has been impossible to make castings of wrought iron or mild steel at the same time solid and retaining their qualities and their strength. Mr. Nordenfelt, the inventor of the well-known machine gun, has recently discovered that solid and perfect castings of wrought iron or mild steel may be obtained without changing the intrinsic quality of the metal by the addition of the metal aluminium, either alone or in the shape of an alloy. The aluminium makes the molten metal more liquid, thus the gases in the metal pass easily away, the metal runs easily into the molds, and a more perfect product is obtained. Even a minute quantity of metallic aluminium added to the molten iron has an appreciable influence.

Perfect castings of considerable ductility and great tensile strength have been made from the softest wrought iron. The iron or steel is melted in crucibles, converters, or metal smelting furnaces of any description, and the addition of the aluminium or alloy of aluminium is made to the metal when molten, shortly before it is to be poured. The addition may, however, be made earlier. It is convenient to provide a plug in the cover of the crucible, which is removed when the metal is completely melted; a tube is inserted into the aperture, and the aluminium to be added is passed down the tube. The tube is removed and the plug replaced, and the metal is soon ready for pouring.

Another important advantage gained by this addition to the iron or steel is the reduction of the temperature at which the wrought iron fuses—about 4000° Fahr.—as it is in this very great heat which is required for melting wrought iron that the absorption of the gases is brought about, which so materially affect the quality of the castings.

The patent which covers this improvement is known as

The Mitis Patent.

And the product as mitis castings. In making these castings only an exceedingly small quantity of aluminium is employed—about 5-100 of one per cent. This small percentage is added in the form of an iron alloy, consisting of about eight per cent of pure aluminium. On the addition of this alloy, the fusing point is at once reduced, as above, and the alloy becomes extremely fluid, so much so that it can be cast in the finest molds, while the great difference between its temperature and its fusing point gives all the time necessary for manipulating it without danger of its solidifying. The extreme fluidity of the charge allows the ready escape of the gases, which otherwise would make a porous casting, while now the result is a remarkably fine, solid and tough casting of wrought-iron.

These mitis castings are said to be 30 to 50 per cent stronger than the iron from which they are made, but though aluminium undoubtedly greatly increases the strength of most of the metals with which it alloys, it is not credited with the increase of strength in this case, for it is said that if the mitis metal is subjected to the process of hammering it, loses its increase in strength and returns to the fibrous appearance and to the strength of the original iron.

Referring to this process the *Engineering and Mining Journal* says that this utilization of this well known property of an aluminium alloy to lower the fusing of temperature of the iron is a very neat and clever application of a curious phenomenon. In rendering the metal more fluid it also obviates the necessity of using those extremely high heats that now cause the steel to melt and run into the molding sand.

A Company Formed to Utilize the Discovery.

The telegraph of the 10th inst. announces the fact that a company has just been formed in New York, consisting of prominent capitalists engaged in iron manufacture and cognate industries to utilize this method of casting wrought iron. The dispatch says that the process is also adapted to the making of steel ingots. It is a foreign patent, controlled by Nordenfelt, the Swedish gun founder and torpedo manufacturer.

THE STRENGTH OF GRANITE.—While tests have been made to ascertain the resistance of granite to pressure, too much dependence must not be placed on the results given in text-books. Granite has a cleavage the same as sandstone, although this opinion would be condemned by the orthodox geologist, as it touches on the theory of granite being an igneous and not an aqueous rock. I mention this but to reiterate what I have before asserted as to sandstone—namely, that to use granite so as to get the greatest resistance to pressure, the stone should be used so that the force should be at right angles to the cleavage or bed of the materials. Granite, like sandstone, laid upon its natural bed, will increase in strength in the ratio of its superficies. However, if granite is fairly bedded on an equal and resisting founda-

tion, no load can in ordinary circumstances crush it. It may be safe enough, in dealing with granite, to take from 684 to 848 tons per square foot as a fair test of its strength.—*James Govans.*

Evidences of Mechanical Progress.

There are many evidences of recent progress in mechanical matters, and one needs to be a close observer to keep well informed of changes that are being made. Every line of manufacturing has its improvements, which must be observed from within, but there are not a few matters of mechanical progress that are plainly open to the public. He who travels by rail may notice that locomotives are being built heavier, and are drawing longer and more heavily loaded cars; also that speeds of trains are increasing. The absence of clouds of smoke and cinders blowing in the faces of passengers can be traced usually to the extension of smoke-boxes and better draft appliances, which are being adopted by most progressive railroads. As the traveler is whirled through the country after dark in an easy comfortable seat on a car finished in artistic style, he observes that cities and villages whose streets were formerly outlined only by rows of dim gas lights have become brilliantly illuminated by clusters of electric lights on tall poles. The web perfecting printing press that a few years ago was believed to be the acme of mechanical skill in that direction has been much improved and, it is believed, will be brought to still greater efficiency. Higher pressures of steam are being carried both on locomotives and on marine boilers. Inside the shop, where master minds are planning these elements of progress, more powerful and efficient tools are being used in turning, boring and cutting metal than were to be had even a few months ago. Machinery is being devised to do what has almost always been done by hand in the foundry and the boiler shop. Mechanics who carefully study what has been achieved by others are the ones who participate in bringing about these progressive changes that are of so much value to the public at large.—*American Machinist.*

A DIFFICULT WELDING.—Foreman Bell of the Boston navy yard forge shop has just completed successfully the largest and most difficult piece of welding ever done in this country. During the last gale the Belgian steamship *Pieter De Coninck* suffered severely, having the massive sternpost to which the rudder is attached sprung and broken. This post of iron is 10x9 inches in thickness, and required to repair it larger forges and hammers than are to be found in this vicinity, it was thought it would have to be sent to Nashua, N. H., to be welded together. However, Mr. Bell constructed large temporary forges, and made his hammers available by an ingenious arrangement of pulleys, etc. The arrangements were completed last Saturday, and on Monday the work was done. Mr. James Wallace, of New York, directed the work. The iron was heated in ten minutes, and for ten or fifteen minutes after the hammer was at work and the work was finished. The picture, seen dimly through the smoky atmosphere, the showers of sparks lighting the dark faces of the workmen, while the whole building shook with the heavy blows struck, was very impressive. About 200 spectators were present, mechanic friends of the workmen and others, and were much gratified with the success of the achievement. Messrs. Bell and Wallace were showered with congratulations for their work.

TALLOW AS A CYLINDER LUBRICANT.—The *Mechanical Engineer* recites the following facts, which should be known to every engineer and mechanic: Some engineers still use tallow as a cylinder lubricant, but they do so at the risk of destroying the surfaces of valve-seats, piston-rings and even the cylinder itself. This is, by reason of the nature of tallow, which is a compound of several fatty acids, oleic, stearic, margaric, etc. It is erroneously supposed that pure grease is the base of all tallow, and that the acids, so-called, are, in some way, incorporated in the process of rendering. No system of refining can eliminate the acid without destroying or neutralizing the grease itself, in a measureaponifying, or turning it into soap. Clear oil is often used by engineers, and an old tin pot set upon the steam-chest is a familiar sight in many engine-rooms, but the evil is not remedied, and the danger to surfaces remains. The steam heat decomposes the tallow or suet, and sets free, or renders active, the fatty acids with the result set forth. The only value in tallow as a lubricant lies in its heavy body, which permits it to remain in contact with surfaces under pressure, but the same object can be attained with mineral oils that are free from adulteration with animal fats.

TRANSPARENT CEMENT.—A French authority gives the following recipe for transparent cement. The advantage claimed is the absence of the slightest yellow tinge, so that the addition of the cement is imperceptible, while it possesses an extreme degree of tenacity: Mix in a well-stoppered bottle ten drams of chloroform with twelve and one-half drams of non-vulcanized caoutchouc in small pieces. The solution is easily effected, and when finished add two and one-half drams of mastic, and let the whole macerate from eight to ten days, shaking the mixture from time to time, but without heat. A perfectly white and very adhesive cement is thus produced.

SCIENTIFIC PROGRESS.

Tornado Predictions.

The Signal Service Bureau is gradually enlarging its sphere of usefulness. It already embraces the condition of the crops in some of its reports, notably on this coast, and it is now proposed that it should inaugurate a special system of tornado signals by which the country, where these destructive electrical disturbances are most frequent, may be warned of their approach by telegraph. Tornadoes are not largely influenced by the laws which govern ordinary storms. The condition of the barometer cannot be relied upon as a means of predicting their appearance, and the ordinary weather signals are quite too slow in giving any useful warning. The disturbing and destroying element in the case of tornadoes is electricity—they are electrical storms—and nothing but electricity is active enough to give the necessary warning. The following item, which we clip from an exchange, will be read with interest in view of the recent tornado which visited Kansas City, and the effects of which men felt for many hundred miles to the east of that point:

Mr. Wm. A. Eddy, of the United States Signal Service, who has given much attention to the phenomena of tornadoes, confirms the opinion of Lient. Finley that our knowledge of these destructive disturbances has been so far advanced by the careful study of the data industriously collected during the past few years, that already predictions of their occurrence may be made with a considerable degree of accuracy.

On the authority of the *Kansas City Review*, we may state in this connection that of 38 predictions that tornadoes would occur in April and June of last year, 18 were verified; of 19 predictions in June and July, 15 were generally verified; and where the characteristic tornadoes failed to arrive, violent wind and hail storms partially fulfilled the prophecy.

Mr. Eddy proposes that a system of tornado signals shall be established at every telegraph station in the States subject to the visitation of these destructive agencies. The necessary addition to the outlay of the service for this purpose would not be large, and the probability is strong that the saving of life and property that would follow the establishment of this system proposed by Mr. Eddy would fully justify it. Even as an experiment, the Government should not hesitate in a matter of such possible importance to a large portion of the country to give it a trial.

THE NEW NEBULA IN THE PLEIADES.—The nebula discovered by the Henry brothers of the Paris observatory, upon their photographic negative of the Pleiades taken Nov. 16, 1885, has been seen—now that its existence is known—without great difficulty, by Perrotin and his assistants at Nice, and by Struve with his new 30-inch Clark objective, and also with the 15-inch at Pulkowa. Struve gives a careful description of the nebula, accompanied by a sketch, in the *Astronomische Nachrichten* (No. 2719), and from his observations it seems probable that some of the small stars in the immediate neighborhood may prove to be interesting variables. The nebula is of a characteristic spiral form, and seems to "escape" from the star Maia. Professor Pickering, upon the announcement of the discovery, recalled the circumstance that certain irregularities had been noticed in a photograph of the Pleiades taken on Nov. 3, 1885, at Harvard college observatory. These irregularities, which had been referred to defects in the photographic process, correspond closely with the descriptions of the nebula, and no doubt represent light photographically visible near Maia. "The explanation thus afforded, of one of the markings on the Cambridge photograph, makes the others of more interest than seemed at first to belong to them. There are indications of nebulous light about Merope; four short parallel streaks directed to the south following side are particularly noticeable, and a faint prolongation of diffuse light may be suspected towards the south in agreement with the description usually given of the visible nebula in that region. There is also a faint streak of light projecting from Electra on the following side * * * No nebulous light is noticeable about Alcyone, Atlas, Pleione, or Taygeta."—*Science.*

LAWS OF MOTION.—The following are the results given in *Nature* of a very elaborate mathematical inquiry, which Professor N. Joukowski has recently made into the laws of motion of a solid body, having hollows filled up with a homogeneous liquid. Various shapes of hollows filled with liquid have been considered, as also the case of a vortex motion of the liquid having interior friction. Some phenomena of the interior motion of the liquid itself, in the case of the solid body when caused to rotate, were verified by experiments which proved conformable to the theory; they have shown that in a body whose rotation velocity is decreasing from its surface to the center (e. g., a glass sphere filled with water, and which is brought into motion), the molecules flow from the poles to the equator, and vice versa where, the rotation being suddenly stopped, the speed of rotation is on the decrease from the center to the circumference. The general conclusion of the inquiry is that if we have a hollow body filled with a liquid, and this system be brought into

motion, its motion will tend to reach a limit characterized by one of the chief axes of inertia of the body taking the direction of the chief momentum of the communicated motion, and the whole system will rotate around this axis as a single body, the speed of rotation being constant and equal to the quotient obtained from the division of the forces applied by the momentum of inertia of the system with regard to this axis. M. Joukowski asks: "Does it not explain the circumstance that our planets, notwithstanding the variety of their occasional primary velocities, all rotate around their axis of inertia?"

A PHENOMENON EXPLAINED.—Remark upon what appears to be the unusual size of the sun and moon, in rising or setting, Strobant points out the common error that intervening objects enable an observer to better estimate the real size of the heavenly bodies, in that the same effect is visible at sea, and indicates the fallacy of several other theories. There are, he asserts, two real causes of the phenomenon in question, both purely physiological—one, the greater sensitiveness of the eye to angular magnitudes near the horizon; the other, a direct effect of the feeble light in the enlargement of the pupil, which, it would seem, tends to magnify objects, even when artificially produced. Thus it is shown by experiments that the distance between two luminous points within a room suffers the same apparent change as in the constellations when, without altering the distance from the eye, the altitude is gradually increased.

TIDES ON THE ATLANTIC COAST.—The great tidal wave which makes nearly two complete circuits of the globe in every 24 hours, is very slight in mid-ocean, but increases in height in traversing shallow soundings, and is still further augmented by converging coast lines. The eastern coast of North America has, as laid down by Bache, a great "southern bay" between Florida and Cape Hatteras, a "middle bay" between Hatteras and Nantucket, and an "eastern bay" north of Nantucket, and while at Southern Florida the tide is 1 to 1½ feet, at Cape Hatteras 2 feet, at southeast Nantucket only 1 foot, the height within the "southern bay" at Savannah is 7 feet, in the "middle," at the entrance of New York bay, 5 feet, and in the "eastern," at Boston, 10 feet, and in the narrow bay of Fundy from 40 to 70 feet.

WATER PURIFIED BY AERATION.—A good deal of attention has recently been given to experiments for the purification of water by aeration, which is the act of combining with carbonic acid, formerly called fixed air. The method is well known to be based on the discovery that the action of air in purifying water is greatly increased by mixing the air and water under pressure. A Fairmount, Philadelphia, turbine engine was converted into an air-pump, which delivered 20 per cent by volume of free air into the water main, this being the proportion found necessary to surcharge the water. Analysis showed that the quantity of free oxygen in the aerated water was 17 per cent greater than before aeration, while the quantity of carbonic acid was 53 per cent greater, and that of the total dissolved gases was 16 per cent greater.

WOODY TISSUES.—The arrangements of fibers and woody tissues in palms and grasses are peculiar and interesting. As an example of the former, the rattan may be mentioned, which runs along on other vegetation for thousands of feet. Here we see the wood, not in a compact form, but scattered with the fibers. In the case of bamboo the fibers form an exterior layer inside of which is a layer of fiber mixed with a good deal of wood. The lightest and most flexible fishing rods are made of these stems with the inner woody layer removed.

WAVE INFLUENCE.—It has been a matter of scientific speculation for years as to how far beneath the surface the roll of the ocean could be felt. A diver who has been down to the Oregon, nearly 200 feet below the surface, says that in one of the alleyways between the houses on the deck he seized a trunk, and, while trying to make fast to it and send it up the surface, the roll of the sea continually swept him and the trunk athwartships. There was a storm coming up at the time.

TENSILE STRENGTH OF ICE.—Herr Fruhling of Konigsberg, has given the tensile strength of ice at 23 degrees Fahr. as between 142 pounds and 233 pounds per square inch. Its compressive strength, found by cubes of over two inches at the same temperature, varied between 61 pounds and 204.8 pounds, a mean being 148 pounds per square inch. The small boy knows perfectly the average transverse strength of ice in thin sheets, and that without any elaborate investigation.

FLEXIBLE GLASS.—Paper of proper thickness is rendered transparent by soaking in copal varnish. When dry, it is polished, rubbed with pumice-stone and a layer of soluble glass is applied and rubbed with salt. It is stated that the surface is as perfect as glass.

THE AETERIDS, SO FAR AS KNOWN, NOW NUMBER 257. Dr. Palisa, of Vienna, discovered the last one of the number on the 5th of April. In our school-boy days, sixty years ago, the number was four—Ceres, Pallas, Vesta and Juno,

USEFUL INFORMATION.

Water Color Painting on Silk.

As there is just now a great craze for painting in water colors on silk, the following directions as to how to do it may be of interest: The right silk to use for painting upon is gros grain of a good quality. The silk should be well strained on a frame and sized with either gilders' size, isinglass size, or colorless gelatine dissolved and diluted with water. Should the silk slacken in the frame after the size has been applied to it, it must be taken out, restretched, and another coat of size given to it. Drawing pins are the best things to use in fastening the silk to the frame; they should be put in close together, almost touching. The outline of the design should be traced upon tracing paper and transferred to the silk, using red carbonized paper and marking the outlines through with a fine crochet needle point. When the outlines of the design are clearly marked out, go over them with a brush filled with Chinese white and megilp, and afterwards fill all the design in with a wash of Chinese white and megilp, going over every part without reference to the color afterwards to be painted. Then paint your design, coloring it as wished. When painting it very light colors and shades, mix them with a little turpentine and copal varnish instead of megilp; for the darker tints use megilp. Mix nearly all the colors with Chinese white, paint as in body colors, putting few shades or tints in, and making those strong and light; too much fine work, shading and painting up gives a patchy, blotchy effect to the painting and spoils it at once. Put in autumn tinted grasses and leaves behind the gaily tinted flowers. These serve to give a background to the picture and much improve it. They are painted with the wash of Chinese white and one tint of Indian red, neutral tint or light red passed over them. A "fixatif" to be blown on after the painting is finished, is considered to preserve and set water color drawings, but it is hardly necessary to employ it when size and megilp have been used. Whits wax is sometimes applied to water color painting; it gives a highly polished appearance to the painting. It is well diluted in alcohol until it is as thin as milk, then brush over the work with a varnish brush, and when dry rubbed with a silk handkerchief.

STEAM HEATING.—It is an interesting fact that while a large number of towns in the United States have steam heating companies in operation, none of them publicly report that a profit is being made. This fact has occasioned some surprise, and not long since we had opportunity to ask some questions, of persons who are supposed to know, in regard to the inside workings of the companies. One of them, it was said, is making money, but it is supplying gas to the town as well as steam, and as the accounts of both departments are kept together, it cannot be said that the steam heating pays. This company has a greatly reduced outlay, because its managers were experienced in pipe-laying before they undertook supplying steam. The experience of the different companies, even if known, could hardly be a reliable guide to others attempting business. No two of the companies seem to have found their greatest losses from similar causes, and yet there is sufficient similarity to make some conclusions plain. A reliable steam meter is much needed. Without this the work will be anything but profitable, no matter how the companies may be managed.

STILL ANOTHER NEW TELEPHONE.—Mr. J. T. Guthrie, of Leesburg, Ohio, has invented a telephone which has been tested by many different parties, and it is said, all claim for it the superiority it possesses over other inventions. This telephone is operated by a distinct current of electricity, and not by induced currents, as are others, and no induction coils are needed. The articulation of speech is made by a natural and mechanical disturbance of the current of the positive and negative poles, which are brought near to or in contact with the diaphragm. One pole is made of a close and compact natural production of the earth, and is a good conductor; the other pole is of an open and porous nature, and not a good conductor; consequently the natural and unnatural poles make a natural disturbance, making it the most sensitive transmitter possible to make. The transmission is made by the disturbance of the electrical current at the poles by opening and closing the circuit (as is the case in telegraphy), which is done in his system by simply speaking against the diaphragm, which causes the current to open at every sound uttered against it.

THE PASSAGE OF STEAM.—The passage of steam into either end of a cylinder may be very distinctly heard by putting a rule, a piece of wood or a piece of iron between the teeth, stopping the ears with the fingers, and putting the free end of the piece of wood or iron against the cylinder. Both ends of the cylinder may be "heard" in turn; both pillow blocks may be tested in the same manner for lost motion, and the steam chest may be tried for lost motion in the valve connection. A great deal is to be learned by "hearing through the teeth;" try it.

TOADS AS BEE EATERS.—The toad may be useful in kitchen gardens as a slug and insect destroyer; the freer you can keep your apary

from his presence, the better. Toads will wait at the foot of a hive to seize any honey-laden bee that may happen to fall to the ground on its return from foraging, and one bee master, says a correspondent of the London Graphic, saw over a dozen little workers captured in the space of half an hour by an old fat fellow, who darted out his tongue with wonderful celerity, immediately he saw a bee on this ground. The bees had been collecting pollen, and many of them, being heavily laden, were unable to reach the floor board of the hive.

PHOTOGRAPHING IN THE DARK.—With a lens made of rock salt, it may be possible to photograph in the dark. The *Photographic News* states that Abney has succeeded in preparing plates which are sensitive to the rays lying beyond the red end of the spectrum, the dark heat rays, and with such plates used with a rock salt lens, there should be a possibility of photographing bodies which possess a high temperature, although that temperature may be far below that needed to render them self-luminous.

DETECTION OF MINUTE TRACES OF COLOR.—Interesting experiments have been made by E. L. Nichols on the quantity of coloring matter which must be mixed with a perfectly white powder (carbonate of magnesia) before the human eye can detect it. From these experiments it appears that red and yellow are most easily detected, 16 and 17 parts respectively being sufficient for detection when mixed with one hundred million parts of white powder.

HORSE-POWER.—The term horse-power is incorrect, because it does not express the actual power of an average, or even an exceptional horse. This really makes no difference. The animal should be entirely eliminated from the mind, and the term taken at its exact meaning, viz., the raising of 33,000 pounds one foot high in one minute of time. A horse would fall far short of doing this for ten hours a day; a steam engine will do it for 24 hours.

A COSTLY TEMPLE.—St. Peter's Cathedral, just finished at Moscow, has five cupolas, and 900 pounds of gold were used in overlaying them. The doors of the temple cost \$310,000, and the marble floors \$1,500,000.

THE COMPARATIVE COST.—The United States and Germany have about the same number of war vessels, yet our navy cost us \$17,292,601 during 1884, while the Germans expended on theirs but \$6,752,094.

THE KNIGHTS OF LABOR count among their colleagues one Governor, one United States Senator, three Congressmen and 125 members of State Legislatures.

GOOD HEALTH.

Baths and Bathing.

Ancient history, both sacred and profane, frequently tells of the baths used of old as a means of health, refreshment and luxury. Pharaoh's daughter went to the banks of the Nile to perform her ablutions. The classic poem describes Andromache as having a warm bath awaiting Hector, when he should return from battle. Penelope, as a panacea for her distress, because of the protracted absence of her husband, availed herself of the soothing bath. Some of the most beautiful figures of the Bible describe the bath, as it was applied at the time when the Saviour was on earth and during the patriarchal age. Ablutions and immersions were undertaken as a method of purification.

The ancient baths of the Egyptians and Persians were famous for having brought every artificial aid refined sensuality could suggest to make them luxurious; and the Roman baths, wherein the old philosophers passed so much time in alternating ablutions, with conversation and athletic exercise, have been described by novelist and historian.

Hot Air Bathing.

Hot air bathing, though highly estimated by the inhabitants of Greece, Rome, Turkey and Russia thousands of years ago, had apparently been unpracticed by the people of England until 1854, when David Urquhart and Dr. Richard Baxter introduced the dry bath into Great Britain. Since then few of the principal cities of that country have establishments for giving Turkish baths. Dr. Shepherd first introduced the Turkish bath in this country.

At this season of the year, when the first natural instinct is to keep the body cool, fresh and sweet, the bath is a grateful topic, especially since it has been brought to such a pitch of marvellous perfection. All persons should be made to understand how the sluggish impurities of their blood may be so moved, their spirits raised, their systems toned up, and (precious boon to women) their complexions cleared and beautified by frequent and judicious recourse to the hot air bath.

No intelligent person needs instruction concerning the functions of the skin—that wonderful regulator of the body it encloses; nevertheless an occasional ordinary bath, or a sponging off is too often supposed sufficient for the maintenance of cleanliness. It is a hideous and lamentable truth that the majority of persons are

never thoroughly clean, and never perfectly realize the importance of keeping the skin in an active state.

Those who have not had the impurities of their systems gently expelled by the hot air bath, are always amazed and sometimes appalled in the first trial by the amount of "scarf skin" which is rubbed off during the process. Indeed, they are quite apt to leave the bath, reflecting with the poet:

"Tis clear that Nature doth require,
Seasons and times of cleansing, which, perforce,
I, her frail son, among my brother mortals,
Straightway must give attendance to."

Horace Greeley once said that he never arrived at the dignity of being perfectly clean until he took a hot-air bath.—*E. r.*

How and When to Eat.

Directions for Perenns Delectans of Avoiding Indigestion.

Never eat food when not needed, simply to save it, for in doing so, it is twice wasted. It is thrown away in the stomach, as it is not transformed into health and strength, but becomes a source of disease and suffering. It had better be thrown upon the land, to reappear in the form of vegetation.

Never eat at bedtime, nor when very much exhausted, nor in great haste, for in so doing the seeds of dyspepsia are easily sown. If you have not time to eat a fair meal properly, you will gain by eating just what you can eat like an intelligent being, taking it so moderately that it may be well chewed and mixed with saliva, so that it may be digested, as that only is of any importance in the promotion of health and strength.

Never harbor the foolish and absurd idea that the richer your food is in grease, spices, the sweets and the like, the more nourishing it will be; for the plainer food contains the most available nourishment, bread being the "staff of life." The complicated dishes are often so difficult of digestion that even less strength is obtained from them than from one-half of the quantity of plain and substantial food, while some kinds of so-called rich foods exhaust more strength—in the vain attempt to digest them—than they can afford, making an actual loss!

Never hurry unnecessarily, or attempt to do more labor than you can fairly do, unless sure of having ample time in the future to rectify errors or to be sick!

Never eat between meals, not even of fruits, if you are at all troubled with indigestion or are willing to become a dyspeptic at some time. No amount of hard work will justify lunches, as the stomach cannot digest food when taken so irregularly, nor well dispose of more than three meals each day.

Never take ice cream or ice water at your meals, or during the digestion of them—within four hours after taking them—when satisfied that a "cold dinner" will prove unfavorable in your case, as ordinary food is never half as cold as these articles! (It is not necessary to be governed wholly by our tastes, especially when that is vitiated by bad habits.)—*Golden Rule.*

Wheat Meal—Its Preparation and Healthfulness.

R. T. G. writes to the *Dietetic Reformer* that he has induced his miller to produce wheat meal ground as finely as possible, without injury to its baking quality, which it appears is done by what is technically called "low grinding," i. e., setting the millstones too close. I enclose a sample and also a specimen of the bread we make from it, by means of soda and buttermilk, baking at a low temperature. It is the best bread I have ever met with. The meal is made from fine white wheat. I place this bread at the head of all articles of food.

I am more and more surprised, by lengthened experience, at the small quantity of food necessary after the period of our growths had passed. I used to think that stimulants were the chief cause of the undue shortening of human life, but am now convinced that infinitely more damage is done by ignorance of the amount of food required to make good the wear and tear of our bodies. When the appetite fails, we take to condiments, sweets and intoxicants, thereby inducing gout, rheumatism and various other diseases. I have seen, perhaps, 100 men of my acquaintance cut off at 50 or 60, in the very height of their usefulness, simply because they thought it necessary to eat as much after 30 as while growing. * * * I am strongly of opinion that the most suitable as well as enjoyable food for those who do not live by the sweat of their brow, is a combination of grain and fruit, with milk, butter, tea, coffee, eggs, by way of luxuries. Upon such food I live, at the age of 57, more mental and almost as much physical vigor, as at any former period of my life.

ARSENIC AND MALARIA.—S. H. Davey of Cornwall, England, confirms Dr. Tomassi Crudelli's opinion concerning the effect of arsenic in preventing cholera and other zymotic diseases. Although during the last 40 years many cases of cholera, fever, smallpox, etc., have occurred in the country surrounding the extensive arsenic works at Bissoe, not a single case has been known within about two miles of the source of the deadly fumes.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

SUTTER CREEK.—Cor. Amador *Ledger*, May 15: The prospects of starting the Mahoney are less encouraging now than for a long time. Over a month of good weather has passed, and still nothing done, and from all indications nothing will be done. G. W. Horn, the foreman, has gone to his home in Sonoma county, in all probability to remain. E. Harrington is still here, but gives little hope of starting. The Wildman mine has been bonded by John Tregloan, sen., for 90 days. From what can be learned the property was bonded in the hope that the Mahoney would be worked, which would facilitate the working of the Wildman. In the event of the Mahoney failing to start up, the Wildman is also likely to come to naught. Drifting at the Eureka is progressing satisfactorily. The course is now east, with the intention of striking the hanging wall. The Lincoln mill is running to its full capacity, with plenty of rock in sight to run for a long time yet. The boys were paid off this week.

RUNNING BY WATER POWER.—Grass Valley *Union*, May 13: The Empire pumping and hoisting works are now running regularly by water power, and there will be no further use for steam, barring accidents to the water supply which are not likely to occur. The water-pipe line, which is over 13,000 feet in length, is found to be perfect in all its parts, there having been but slight leaks, which have been closed, when discovered. Since the water was turned on, the pipe-line has been carefully inspected day after day, and it is found to have been laid down in a superior manner. The water will be turned on at the mill as soon as the additional head of twenty stamps are ready to drop. Three 6-foot Pelton wheels are used for the respective duties of hoisting, pumping and milling.

MORE WATER POWER.—Now that water-power has been introduced to the Empire mining works, the next move will be to extend a 13-inch pipe-line from the Empire to the North Star mine. This mine will be connected directly with the 22-inch main line, which will give at the North Star a pressure of over 650 feet from the source at the head of the main line. The contract for laying this line has not been made yet, but it is expected to be in a short time, and the work will be completed in the next few months.

El Dorado.

GOLD.—Placer *Herald*, May 15: One day last week 122 ounces of gold were brought to Auburn from the Zangraf quartz mine near Wild Goose Flat, El Dorado county, being the result of three weeks' run. This represents about the average yield of the mine.

Inyo.

CERRO GORDO.—Inyo *Register*, May 13: The Ygnacio company has been working quietly, but to some purpose, for several months. "For a fact" they have shown the old mine to be a first-class property. They have opened a bonanza of rich silver-lead, or smelting ores, lying about 400 feet below the old works, and below the Potosi tunnel. During the time they have run over 400 feet of tunnel and drifts, finding ore almost continuously, but taking out none except what was necessary to the progress of the work. The ores (specimens of which we have) are beautiful carbonates and oxides of lead, carrying an average of 50 per cent lead, and 100 ounces silver per ton, as definitely ascertained through constant tests by a competent assayer, S. D. Woodhull, M. E. They have also taken out some 30 tons of 300-oz. silver milling ore from the old upper works, and the old dumps are proving to be a good mine in themselves. Over a hundred tons of fine milling ore have been taken from one of these dumps alone, and three-fourths of it is yet to be sorted over. It is astonishing how much good ore was thrown over in these dumps. Six first-class sorters are kept at work upon them all the time. Geo. Weise is underground foreman, and is said to be a most competent man. Geo. M. Hawley, son of the principal owner, is in general charge. He has a small force at work on a mine called the Aries, which is daily producing a paying quantity of high grade ore. Mr. Gordoites has commended himself to the Cerro Gordoites generally. The Union, Omega, Uncle Sam and several other mines, are producing considerable quantities of lead ores, most of which is shipped to San Francisco. Altogether, mining prospects in Cerro Gordo are very encouraging.

PANAMINT.—*Independent*, May 15: A good deal of progress has been made on the rebuilding of the works at Panamint. The mill frame is nearly completed and much of the machinery is in place. A great deal of labor was required repairing damage done to machinery by the fire that destroyed the works years ago. A good deal of new shuffling, steins, cams, shoes and dies will be required. The mortars are as good as ever. The engine and boilers have been put in thorough repair and are ready for work at any time. During the winter months much delay was caused in getting in freight by snow on the mountains. Now work can be pushed more rapidly. A shipment of a few tons of ore was made last Saturday, from a prospect belonging to J. C. Irwin, and located east of Alford. Barnes & Kehoe made a shipment of two carloads of ore this week. Kehoe reports the mine looking well, and the probabilities are that another shipment will soon be made.

Napa.

WORK RESUMED.—*Calistogan*, May 15: Work has been resumed in the long tunnel on the Red Cloud claim in King canyon, owned by Dr. Smith and others. Three men are employed, and we understand that others will be set to work soon. A miners' house, 12x20 feet, is also being erected on the claim for the accommodation of workmen. The tunnel, if we remember correctly, is 80 feet long in very hard rock, and it is supposed that by drifting 60 feet further, at most, the desired vein of ore will be cut. We hope the parties interested in the work will meet with success.

Nevada.

BOSTON.—Grass Valley *Union*, May 9: After fighting water for some weeks, which increased greatly from the heavy rains of April, underground work has been resumed in the Boston mine, and the shaft below the 230 level is being sunk for another level. The rock in the shaft is rich in free gold, and the 230 level is showing up finely. Chas. E. Uren, civil engineer, has made a very handsome and elaborate map of the mining properties of the North Banner Consolidated Tunnel Company, showing the extent of the underground workings, mill site, the water-power resources and all the surface surroundings. Frank Chesneau's little 3-stamp quartz mill, on Wolf creek, is running constantly on custom rock. The directors of the Horseshoe Mining Company will hold a meeting in a few days and determine upon the time of starting up the mine which has lain idle during the winter. It is thought that work will be resumed between the 1st and 10th of June. The pumping and hoisting works are in good condition for service.

SLATE LEDGE MINE.—*Tidings*, May 14: Francis & Co. are working the Slate Ledge mine (Perrin's) under a lease. They find the ground there very easily worked and the ore can be cheaply mined. The ledge is about four feet thick. In a week's time the miners have taken out 40 loads, and the estimate of good judges is that none of it will pay less than \$30 a load and some of it will pay \$50 a load. We call that a pretty good show for a mine.

Placer.

PAYING.—Placer *Republican*, May 12: The Zangraf mine down on the American river continues to pay well and is one of the best mining properties near Auburn. With the exception of the dry weather in the summer, when water is scarce, it has continued to pay handsomely at every cleanup since January, 1883. Last Thursday 122 ounces were brought in from the mine from a three weeks' run. On April 16th the cleanup returned 101 ounces, on March 24th, 91 ounces, and on March 3d, 119 ounces. The cleanups are made about once in three weeks and average about the same as the above figures. The Bob Lewis mine at Damascus is still turning out rich gravel that pays from \$8 to \$10 a carload. Work in the Mountain Gate mine is being pushed with the usual good results, and rich gravel has been struck in the Lebanon mine at Prospect Hill. The difficulties between the owners of the Big Oak Tree and Rising Sun mines at Colfax have been settled by pooling the properties and placing the whole under the management of W. B. Hayford, with the privilege of sale.

San Bernardino.

DAGGETT.—Cor. Calico *Print*, May 15: The news from Rattler district, 30 miles south of Cadiz station on the A. & P. R. R., is encouraging, so Mr. Heald, the secretary of the company, informs me. The mill is working well, but lacks capacity, and 5 stamps will be added immediately. In the waiting for the enlargement of the mill the force of men from the mine are engaged sinking on the well for the larger supply of water which will be needed. Robt. McCueston's teams are making two trips daily hauling lumber and machinery for the Runover mill. The Daggett mill is pounding away on Blackfoot rock this week. Some work also doing at the Sampling Works. The Oro Grande mill keeps constantly at work on Waterloo ore with good results. Your correspondent was shown by C. J. Perkins some lead buttons taken from some newly discovered mines, about six miles east from Keene's station in the Tehachapi range. The ledges are said to be very large and well defined, carrying over 50 per cent lead and about \$20 silver per ton, with plenty of wood and water in the near vicinity. Mr. Perkins left last Monday to take a look over the property. Rumor has it that J. B. Osborne has gone to San Francisco to conclude a sale of his Ord and other property. Should they be realized, Daggett would be the main reduction and shipping point, adding greatly to our already large shipments of bullion from Calico and surrounding camps, for there are thousands of tons of medium copper, silver and gold ores already extracted, and in sight in some dozen or more huge ledges upon which a great amount of sinking and tunneling has been done. Old Ord is almost a mountain of ore, and when she does commence she will make things lively.

Sierra.

THE COLOMBO.—*Tribune*, May 15: The contractors at the Colombo mine completed the raise the first part of this week. Everything concerning the mine is kept very quiet, but, nevertheless, it has leaked out that the ledge is looking fine and that there is, beyond all doubt, enough in sight to warrant the company in resuming operations. We are informed that as the raise is now through, men will be put on to drive ahead on the ledge. Arnott, Moore & Co. are making preparations to start a tunnel at their gravel claim between Eureka and Brandy City. They will have to run about 3000 feet to reach the channel at the point where they intend to tap it. Ingersoll drills will be used in the work.

Siskiyou.

ORI FINO.—Cor. Yreka *Union*, May 15: Since my last writing, having a little leisure time, occupied the same by taking a stroll in and around the quartz mines of this place. The first that came under my observation was the one owned by Messrs. Ladd and Clemens of New River and D. A. Corson of this place. This ledge was purchased by the aforesaid parties about one year ago. It is a well-defined ledge. About 200 tons of ore have been taken out and crushed within the last year, yielding \$8 per ton. There is considerable ore in sight. The ledge can be traced almost the entire length of the claim, and prospects well wherever tested. The next in order, in an adjoining ridge, is the lode owned and worked by Messrs. Connor, Lenard and Callahan. This mine turns out very good rock, the same being crushed in an arastra near the claim. From former tests and prospects of ore they are now extracting will show a result of \$20 per ton. The next, further up the ridge in a westerly direction, is owned and worked by Messrs. Lindsey & Sons. They have out about 50 tons of ore and intend making a crushing soon, from which they anticipate handsome returns. About a mile farther west is the mine owned by A. M. Johnson. I learn considerable bullion has been taken from the ledge and prospects of much more being taken out. He has out about 100 tons and contemplates hauling and crushing soon; about \$30 a

ton will be the result. There are other ledges in the vicinity of those mentioned, which no doubt would prove remunerative if properly handled. Ori Fino, like many other places, needs capital and energy to thoroughly develop the hidden wealth in and about the place.

Trinity.

DEADWOOD.—Cor. Trinity *Journal*, May 12: The most recent strike is that of Wm. McLiman, jr., and John Kemp on the A. B. mine on Thorn Gulch. From their dump pile I took an average of the ore amounting to three pounds, which yielded \$1.25 in free gold. The ledge is from two inches to one foot in width, carrying well-defined walls. This property was purchased from Otis Collopy and Chas. Clements for the extraordinary sum of fifteen dollars. One week after the purchase they were offered \$7000 for their property by the same parties. All the fools ain't dead yet. Jud and Walter Van Matre are the owners of the most promising mine in Deadwood. The ledge is from six inches to two feet in width in the stopes, which average over \$100 per ton; the formation, reasonably soft, enabling them to extract ore at a very lively rate. Jud was the finder of this little gem, which was discovered near the roots of an oak, and as Jud says himself, it is not for the beautiful shade on that summer's day, perhaps this treasure would be still hidden. Wm. Blagrove is taking out some of the boss ore, and from every indication will for some years to come. Frank Belleau & Co. have suspended work on their mine for a few weeks, making preparations for machinery, etc. Collopy & Kearney leased the Sunrise mine some time ago, and after doing considerable work, in the way of prospecting, are now stopping out \$700 ore from a good-sized ledge. I hear that Geo. Van Matre and Mike Ramm have struck a very rich vein.

Tuolumne.

EXPERIMENTAL.—*Union Democrat*, May 15: The Experimental mine, located in the vicinity of Columbia, was visited some six weeks ago by Mr. Louis Blanding, who made a thorough examination of it, and reported favorably on it to certain parties in San Francisco. The information obtained by him on the ground, and the results of his tests of the ore made on samples taken by himself, convinced him of its present value and future possibilities when properly developed and worked on a large scale. The location is peculiarly good for rapid development and economic and profitable working. The information thus gained and the favorable opinion he expressed came to the knowledge of other parties who acted upon it, and the mine has been conditionally sold for \$33,000 on a bond of four months, as we learn from authentic and reliable source.

STOCKTON MINE.—It is probable that the Stockton mine, situated about a mile from Sonora, and which has experienced quite a spell of idleness, will be restored to activity. The mine is thoroughly equipped, and has yielded some very fair ore. Mr. Mark Lane, of Stockton, one of the owners, has several men engaged in prospecting the mine with a view of further development, and if possible to tap the same. The presence of water in this mine has been a source of great annoyance and expense in its working. If Mr. Lane's tapping project proves successful, avoiding the only obstruction that will be, the mine can be made a very profitable property, even at a low grade of ore, as the machinery for working the mine is all on hand.

A NEW QUARTZ VEIN DISCOVERED.—Hubert Shaw brought to town this week some very good-looking quartz from a vein he discovered about a week or ten days ago. The vein as far as explored is 18 inches wide, and situated six miles from the town of Groveland. The quartz shows good freely, and it is thought will mill about \$30 per ton.

A GOOD STRIKE.—Monday week, Messrs. John Noonan, Capt. Knowls and Ed. Martin struck a \$260 pocket in their mine on Campbell's Flat. Mr. Noonan informs us that the mine is looking very promising, and chances for another pocket very flattering.

CHANGED HANDS.—The Mississippi mine, near Big Oak Flat, upon which a mill has just been erected, has lately changed hands, the former owners, Jutson & Co., having sold the mine to Messrs. Horwell & Co.

NEVADA.

Washoe District.

CHOLLAR.—*Virginia Enterprise*, May 15: The daily expected orders to resume sinking the Chollar-Norcross-Savage on Combination shaft were received, and in compliance therewith work to that effect was actively commenced on Tuesday. The dump has been cleared of accumulated debris and sediment, the pump connections arranged, and the actual work of sinking deeper is now being commenced. The shaft was 3155 feet deep when sinking was suspended, therefore 45 feet farther will carry it to the 3200 level, the present objective point. Thence a drift west and north will be sent out to meet that coming from the bottom of the Hale and Norcross deep winze on the 3200 level. As the bottom of the shaft when it reaches that level will be nearly or quite into the easterly dip of the vein, very little westward working will be required for the Hale and Norcross connection, although it is the intention to push a main west drift or crosscut from the shaft through to the west wall of the ledge. No crosscutting as yet on the 3100 level of Chollar.

SAVAGE.—After a rest of about five years, direct work was resumed in this mine on Wednesday last, at the north line, from the 600 level of the Gould and Curry mine, continuing the main lateral south drift of that mine, which had reached the Savage line. The drift commences from the line in low grade ore, which is expected to develop into something better as the drift progresses. It is to be carried through to connection with the main Savage shaft, the debris removed at present being taken out through the Bonner shaft by arrangement with the Gould and Curry Company. Should circumstances, however, justify, the Savage works will be started up before long, and the regular hoisting, etc., done through it. The Savage Company have been combined with Norcross and Chollar in the deep middle mining explorations, and now they propose having a little side-show of direct work themselves.

POTOSI.—The diamond drill hole, commenced 40 feet north from the face of the main south lateral drift, on the 3100 level, mentioned in last week's report, was sent out 117 feet east into the ore vein,

but it finally got into a peculiar clayland quartz-seamed formation, which clogged and twisted the drill so that it had to be withdrawn for fear of breakage. The drillings showed a considerable quantity of black sulphurets of silver, which was expected, it being the same ore vein which runs through the lower levels of the Hale and Norcross and Chollar. At noon, day before yesterday, the diamond drill was started at a point 75 feet further north, and has now made a good commencement east toward the ore vein. It will be into it shortly, and be sent through to the east wall unless the formation prevents. But little water was found in the other hole, and none in this.

HALE AND NORCROSS.—On the 2900 level the main north lateral drift is gaining near proximity to the Savage south line, and will be continued into that mine when it reaches it. Good indications of a paying ore body are found to the west of this drift and is liable to turn out, as was thought some months ago when work was progressing at this point, to be the making of a genuine paying ore body extending into the Savage. The explorations in the ore body above the 3100 level have extended to the west side of the vein, and from the openings made a good supply of ore can be daily taken out when required. As soon as practicable or expedient the drift from the 3200 level or bottom of the deep winze will be opened and carried through to connection with the Combination shaft, which is now being sunk deeper for that level.

GOULD AND CURRY.—On the 600 level the upraise at the south line, next to the Savage, has reached an altitude of 57 feet above the track floor, the top or face being in low grade ore. It is to be carried through to connection with the old workings on the 400 level. At a point in this upraise, 45 feet above the track floor of the 600 level, crosscuts east and west are started, both in low grade ore or strongly mineralized vein matter. These fine ore bonanza indications developed at that point have induced the Savage Company to run a drift into their mine, or rather to continue this Gould and Curry drift on the 600 level, the privilege being granted by the Curry Company. The drift north in Curry on this level is making good advancement in favorable-looking vein porphyry with seams of quartz and clay.

ALTA.—Crosscutting was commenced last Monday on the 700 level. The face of the main north lateral drift on this level was expected to reach and connect with the old Lady Washington workings by this time, but a resurvey shows that there are a few feet further to go yet. The main west drift from the shaft is 500 feet in length, and the north lateral drift, which was started at or near its face, is 800 feet in length, following along the east side of the ore vein. One hundred and fifty feet from where this main lateral drift leaves the west drift is where the first crosscut was started. It is in ten feet and has cut into a body or streak of good pay ore. Another crosscut (No. 2) west has been started about 40 feet further north, which is in a few feet and is expected to strike the same vein of ore as found in crosscut No. 1.

BEST AND BELCHER.—The water still continues to be held stationary at the point 2335 feet below the surface or collar of the Osbiston shaft, where a tank station has been cut out and a new tank and donkey pump put in operation to aid in deeper operations. This work is completed, and on Monday next the drainage work will be resumed, lowering the water to reach the bottom of the shaft. Meanwhile an air pipe is being carried through to the C. and C. shaft, by way of the Suro tunnel, to bring an air supply from the compressor at the C. and C. works to run the donkey engine.

YELLOW JACKET.—Daily yield 140 tons, keeping the Brunswick mill steadily supplied. The ore from the 1300 level up is worked to advantage by the concentrators in use at the mill, but above the 400 level chloride ore predominates, which no concentrators can save or concentrate. As has already been shown in these columns, patent concentrators are of no use in chloride ores, which compose about seven-eighths of the Comstock ore formation.

CROWN POINT AND BELCHER.—About 375 tons is the present daily yield. The old ore sections are showing fairly, there being enough in sight in the various stopes and breasts to keep the mills running for a year or two at least.

CON. CALIFORNIA AND VIRGINIA.—Daily yield 375 tons, showing a value of about \$12 per ton according to battery sample assays at the Morgan and Eureka mills. On the 1400 level the drift running southwest from the main west drift has been extended 49 feet, making a total length of 848 feet.

MEXICAN.—On the 700 level the north lateral joint Mexican and Union drift from the Ophir shaft has attained a length of 196 feet. The northwest drift from it, in Mexican ground, is in 114 feet. Faces of both drifts in favorable-looking vein matter.

SIERRA NEVADA.—On the 520 level west crosscut No. 2 has been extended 41 feet, making a total present length of 597 feet. The formation continues to be hard quartzite and porphyry, with a slight seepage of water.

UNION CONSOLIDATED.—On the 500 level further explorations are suspended, and work concentrated upon the advancement of the joint drift now being run through the Mexican into this mine.

KENTUCK.—Daily yield, 60 tons of low grade ore from the old upper workings. There is plenty of this ore in sight to run on for the next year or two.

OPHIR.—On the 400 level the crosscut explorations east and west are making good progress, with no new features of interest to record.

MONTE CRISTO.—The drift west from the new shaft, 150 level, is advancing slowly in a very hard quartzite and porphyry formation.

Como District.

MORE ORE.—*Virginia Enterprise*, May 15: Ed. Swift, of Gold Hill, hauled two wagon loads of ore from the Como-Eureka mine, Como, to the Thompson mill, Lower Gold Hill, day before yesterday for reduction, and two more loads yesterday, making in all about 16 tons. This lot has been hauled as a fair sample of the ore in the mine, and its reduction at the mill will give a square test of its general value. The Symonds brothers have been actively exploring and pumping up the mine during the past winter, and show a large dump of fine-looking ore as the result of their labors. It is most certainly

to be hoped that the returns from this test crushing will prove satisfactory and show that there is a second paying mine in Como.

Dun Glen District.

PURCHASED THE BLACK HAWK MILL.—*Silver State*, May 13: Sheriff Fellows disposed of the Black Hawk mill yesterday to S. M. Hendra, of Dun Glen, who intends to remove it to that place to work ores from a gold mine which belongs to him and Steve Thomas.

Eureka District.

ACTIVE OPERATION.—*Eureka Sentinel*, May 15: Work will be resumed at the Richmond reduction works about June 1. Two furnaces will be fired up. The Hecla mine at Mineral Hill, this county, shipped a ton of ore to the Eureka Con. works last Thursday. The roads leading to town from the various sections of Eureka District are now in good hauling condition. From the Whippoorwill mine on Prospect Mountain 3 tons of ore were shipped to the Richmond reduction works last Tuesday. The Comet mine in New York Canyon made a shipment of 2 tons of ore to the Richmond reduction works the other day. Six tons of ore were shipped from the Giant mine on Prospect Mountain to the Richmond works during the first part of the present week. The Kentucky mine on the western slope of Prospect Mountain made a shipment of 1 ton of ore to the Richmond reduction works the other day. Sixteen tons of ore were received at the Richmond reduction works from the Iron Clad mine, Secret Canyon, during the week ended yesterday. But four miners are now employed in the Phoenix mine on Ruby Hill. From the property 26 tons of ore were shipped to the Richmond reduction works during the week ended yesterday. The Lizzie L. and Alexandria mines on Prospect Mountain made shipments of ore during the week ended yesterday to the Eureka Con. works. The former shipped 15½ tons, the latter 3½. It is hardly probable any work will be done in the Albion Con. mines until after the expiration of the time in which the properties as sold by the Sheriff yesterday are subject to redemption. Quite a number of Adams Hill properties have showed up well the past week, the Bowman having shipped to the Richmond reduction works 7 tons, the Frazier and Molino 15 tons and the Bullwhacker 14 tons. Of the Ruby-Dunderberg properties, the Lord Byron and the Dunderberg mines made shipments of ore to the Eureka Con. reduction works during the week ended yesterday. The former sent down 10½ tons, the latter 19. The Marguerita mine on Adams Hill continues to produce good quantities of ore. On Tuesday last 5½ tons were shipped to the Eureka Con. reduction works. The Silver Lick mine, an adjoining property, also made a shipment to the same works of 4½ tons. The work of sinking a double compartment shaft in the Paul Pry mine on Adams Hill, that was commenced ten days ago, is progressing favorably. The outlook for this property, that is said by practical miners to be one of the best in that locality, is very good. The work of excavating a suitable foundation for the new machinery in the Eureka Con. hoisting works is a larger job than many suppose. Even with the large gang of men employed thereon, the work of draining the mine will hardly commence before the 10th of August.

THE ALBION CON. PROPERTIES SOLD.—*Sentinel*, May 15: The mines and other properties of the Albion Consolidated Mining Company were sold yesterday in front of the Courthouse by Sheriff Stinson under and by virtue of an execution issued out of the District Court in and for this county, to satisfy judgments against the corporation to an aggregate of over \$60,000. The Uncle Sam was sold for \$37,000; Albion, No. 1, \$5,000; Albion No. 2, \$5,000; Albion No. 3, \$1,000; Albion Con., \$100; Moss Agate, \$100; Price, \$500; Davis, \$100; the improvements on the Albion and Uncle Sam, \$1,500; improvements on the Price and Davis, \$1,500; Albion hoisting works, \$180; machine shop, \$100; lodging-house, \$400; furnace plant, \$330; brick store, \$500; Uncle Sam shaft-house, \$142.15—making an aggregate of \$58,431.15. With the exception of three or four items, the purchases were by the Richmond company. The above are subject to redemption any time within six months. To make such redemption would cost \$68,948.65.

Freiberg District.

ORE.—*Eureka Sentinel*, May 15: A sack of ore weighing 117 pounds was brought in from one of the mines of Freiberg District, Nye county, to the Eureka Con. works the other day, in order to test its value.

Garfield District.

A RECENT FIND.—*Inyo Independent*, May 15: Very rich ore is being taken from a recent find in Garfield district. The claim is joining the location of Farington Brothers, about 16 miles west from Soda Springs station of the C. & C. railroad. A carload of the ore sent to Selby & Co. netted \$300 a ton. Since then ore has been found that goes from \$500 to \$10,000 a ton.

Jackrabbit District.

DEVELOPING.—*Pioche Record*, May 8: The Onondago claim, being opened up by Wes. Williams at Jackrabbit, is said, by those who have seen it, to be developing grandly. The ore in the ledge is two and a half feet in width, and all express the belief that it is leading to an immense ore body. Out of a dozen or so assays made, the lowest, made from the casing material, went \$17 in silver and 59% lead, and the highest went over \$51 in silver and the highest in lead 74%. The other assays ranged from \$31 to \$48 in silver. At the rate of the price of lead at present, this ore can be shipped to the furnaces in Salt Lake City at an immense profit. This mine, from the character of the ore bodies of that district, is almost certain to develop a huge body. This mine is owned by Williams, Welland & Co.

Jefferson District.

MILL.—*Belmont Courier*, May 8: The Harrison Brothers' mill at Jefferson is running steadily and doing good work.

Northumberland District.

LAST CHANCE.—*Eureka Sentinel*, May 15: Three tons of good ore were received at the Eureka Con. works from the Last Chance mine, Northumberland District, the other day.

Peavine District.

GOLD ROCK.—*Belmont Courier*, May 8: J. R. Seymour brought in some rock on Sunday from

Peavine which he thinks carries gold. It is his intention to have it tested.

Revello District.

NORRIS ORE.—*Eureka Sentinel*, May 15: Half a ton of good ore arrived at the Eureka Con. reduction works from the Norris mine, Revello District, Nye county, on Monday last.

ARIZONA.

TONTON BASIN.—*Cor. Prescott Courier*, May 12: It is reported that Mr. Chas. Bacon and others have made a rich strike of free milling gold near the old Jones quartz mill, on the east fork of the Verde. Parties who have seen the ore pronounce it the finest struck in the basin. It is also rumored that the "Golden Wonder" has changed hands and that a party of capitalists have taken hold of that property who will work it for all that it is worth.

GROOM CREEK.—*The Azlan mill*, on Groom creek, after many interruptions caused by breaking of machinery, is now steadily at work day and night on ore from the Kelley mine. Excavations are being made for placing in position two Triumph concentrators, in addition to the Frue Vanner now in use, the percentage of sulphurets in the ore being so high that a single machine is found insufficient to handle them. A new road has been made from the mine to the mill, along the creek bank, and, as it is all down grade to the mill, large loads of ore are easily hauled. The capacity of the mill is about from 12 to 15 tons per 24 hours, crushed through a 30-mesh screen. No ore has yet been stopped from the mine that is now being milled, some 250 tons having been taken out in doing dead work. Rupert & Sons are running steam arastras on gold ore from a mine situated just above the Arizona Queen Company's mill. The ore is of a very high grade. The lessees of the Nevada mine have cut a face for their new tunnel. We yesterday saw some very fine rock from this ledge, showing fine gold in great abundance.

MONTANA.

NEW MILL.—*Cor. Inter-Mountain*, May 12: The district of Marysville now shows very healthy signs of coming to the front as one of the great producers of the Territory. The wonderful success of the Drum Lummon, under the present management, has been one cause, while the astonishing returns made from the once abandoned Penobscot has been another. The sale of the Empire and other mines four miles from here to an English company, and the continued output of the Glosier and other mines, go to show that the developed lodes are permanent, and frequent strikes confirm the belief that other paying mines will fall into line. Last August John Longmaid purchased the Penobscot and Snowdrift mines; also the mill (ten stamp) and engine. Without pumping one drop of water from the lower levels, in seven months Mr. L. cleaned up in the neighborhood of \$60,000, and it is firmly believed that out of that sum cleared one-half, after paying for the property \$4,000, and for the machinery \$5,500. A new vein discovered on the Snowdrift patent this spring is turning out some very rich gold quartz. The shaft is now 70 feet deep and levels are being run. The 10-stamp mill is busy crushing the output. One-half mile south of the Penobscot, Messrs. Wormer & Elge have built a 3-stamp mill the past winter, and are doing very well on \$28 quartz from the Doc Parker and Griff lodes. The Bald Butte Company, B. H. Tatem, Chumero and the Chadwick Estell owners have a 10-stamp mill, which is run about eight months in the year on quartz from their mines. There are numerous prospects in this vicinity opened out since the Penobscot was found not to be a dead issue that in time will be heard from. These mines and mills are in Deer Lodge county, about four miles from Marysville. On this side the range in Lewis and Clarke county the Mount Pleasant mines, owned by the Charles M. Cotter estate and Wm. Hickey, have been worked on lease the past winter by Messrs. Lynch and Tierney. The 10-stamp mill on this property will start up on the 10th prox. for a summer's run.

DRUMMOND.—*Cor. Butte Miner*, May 12: Twelve miles north of this point lies what is called Sunset mining district, from which we receive glowing accounts daily. Among the rich lodes that are being developed are the Hapardnee and Independent lodes. The former was sold a few days ago to a Chicago company by Messrs. Bowles & Stone, the consideration being \$25,000. This famous gold-bearing lead is being well developed. There are two tunnels, the upper and lower. The depth of these tunnels is in the side of the mountain where this mine is located. The average width of vein of the upper tunnel from mouth to face is four feet—lower tunnel six feet. The purchasers of the mine are W. A. Kowman, W. A. Sargent, of Chicago, Illinois, and Capt. J. Rogers, of Portland, Maine. The parties are well satisfied with their investment. The enterprise is under the management of the former gentleman, W. A. Kowman. According to articles of agreement the company is to have works erected under a limited time—ninety days being specified, I believe. The first shipment of machinery for the works is expected at this point daily. It is not a regular stamp mill, but a pulverizer. The capacity of the works is supposed to be equivalent to a twenty-stamp mill.

NEW AND RICH DISCOVERIES.—Last reports from Dunkelberg Creek mines, south of here, tell us that many new discoveries have been made. Among the distinguished gentlemen that have just arrived from the new fields are Vice-President Oakes, General Manager Buckley, of the Northern Pacific Railroad, F. W. Gilbert, Division Superintendent, and J. B. McMahon, Master Mechanic of the Rocky Mountain Division, and Jop. Tibbetts, a prominent business man of Portland, Oregon. I learn from Mr. Tibbetts that the above-named gentlemen bought a half interest in a group of mines belonging to one Frank Taibass for the sum of \$300. Very little development has been made on the mines, yet among the group is one called the Little Joe, from which some ore was taken which assays as high as 300 ounces in silver and 70 in gold. One hundred and six locations have been made in the last ten days on the creek. Look out for a lively town there before fall. Joseph P. Losse and William Burt, of Pioneer, sold to A. Lambert, a heavy stockholder in the famous Granite mine, a lead on Gold creek for the sum of \$2500. A force of men will be put to work at once.

THE MOULTON.—The Moulton is producing its usual quantity of 50 ounce ore, and during the coming week will start up the Sturtevant mill, which will increase the crushing capacity of the mill to 70 tons per day. The Silver Safe and the Gulch Con. mines, which are being worked in connection with the Moulton are showing up fine bodies of ore at present. Development is the order of the day.

THE MAJOR BUDO TUNNEL.—This tunnel is located about one and one-half miles from Butte, in Park canyon. At a depth of 980 feet a fine body of ore was discovered, lying northeast. The tunnel strikes the vein diagonally. Men are now driving drifts on the vein. The company have in contemplation the erection of a 30-stamp mill upon the property during the coming season.

NEW MEXICO.

LIXIVIATION.—*Black Range*, May 7: C. J. Goff, manager of the Black Range Lixiviation Works, E. H. Russell, inventor of the Russell lixiviating process, and Mr. Wilford, arrived last night, and are making arrangements for the early erection of the new mill. The company heretofore known as the Black Range Milling Company has dissolved and the company putting in the new mill is the Black Range Lixiviation Works, with H. N. Castle, president; E. Wilder, vice-president, and C. J. Goff, general manager. The new works will occupy the same ground as the old mill. The company will put in the best possible machinery required by the lixiviation process obtainable, and will use every effort to make the enterprise a success, which they without doubt will accomplish. Mr. Goff is deserving of much credit for the push and energy he has shown in pushing this enterprise to the front that promises to be of untold value to the Apache and other mining districts in this end of Sierra county, and the mine-owners, to show their appreciation of his toil, should work their properties at once, and take out ore for the mill.

OREGON.

PINE VALLEY MINES.—*Cor. Oregonian*, May 15: Several hundred people have wintered here and have evidently been not altogether idle. Allentown now contains 76 buildings, Cornucopia 46, and there are 18 cabins straggling along the road between the two towns, which are less than half a mile apart, and which will undoubtedly grow together before autumn. Saloons, restaurants and general merchandise stores have trebled in number since last autumn; a brewery is in full operation, a two-stamp sampling mill is in process of erection, and a small sawmill has been built half a mile below town. The mines, or rather the prospects, discovered last year are still buried under the snow, and nothing can be done in the way of exploration or development for six weeks yet. During the winter a few men have been at work on the Contact, or as it is more generally known, the "Silver mine," located on the north and east side of Pine creek about four miles from here, and work has been steadily pushed upon the "Whitman" by the Louisville (Ky.) company, which purchased that mine last fall. Supplies for the Contact were carried up during the winter by packers traveling on snowshoes, but a fairly good road has been constructed to the Whitman. There has been some little work done on a few other claims, but generally it may be said that the Pine creek miners have been hibernating since November last and waiting for the coming season. Doubtless the future of the camp will be determined by the developments made this summer. The showing in the Contact at a depth of 135 feet is said to be that of a true fissure vein of five feet of quartz, with a hanging wall of granite and a foot wall of slate, exhibiting ore averaging over \$100 in silver per ton all the way down. This showing, though extremely satisfactory to the owners of the Contact, is yet of no great consequence to the camp generally, as the Contact is four miles away, in a different formation, shows a different class of ores, and evidently belongs to a different system from that of which Cornucopia and Allentown are the center. Nor can the work done on the Whitman be said to establish the permanency and value of the mines in this district. At 100 feet the drifts in this mine are said to show a four-foot ledge, with 30 inches of good ore, some of which is exceedingly rich, but it will take something more than this to make a "Bodie." The Union, Companion, Red Jacket, Robert Emmet, Red Boy, Mountain Chief, Cox and Allen, Forest Queen, O. R. & N. and other mines which produced from their croppings last summer the rich rock which first turned public attention to the Pine valley mines, are as yet practically undeveloped, and most of them remain in the hands of their original locators. These locators were, in most instances, unacquainted with the modern methods of selling mines; they placed a very high estimate on the value of their prospects, and they did not seem to be aware of the fact that the days when capitalists paid large sums for "the substance of things hoped for, and the evidence of things unseen" have passed by, and that he who expends to induce capital to sink a shaft on a quartz ledge in a new district must give up a large share of the location for the work. Probably the coming season will witness many changes in this respect, and claim-owners will either sell at low figures or else go to work on their claims, and with drill and dynamite put them in a state of development where they can legitimately ask high figures. Again, last year, the snow was an unknown quantity, both as to its depth and as to the time of its advent. Now, however, it is known that the ground will be bare from June to November, and that during the entire winter there will be practically no difficulty in working claims where work shall be fairly under way before the first snowfall. There is a possibility of a great mining city here, with a population of 20,000 people, and a bullion output of \$10,000,000 per annum, and there is a reasonable certainty of a prosperous mining camp of a few hundred people with a bullion yield of several hundred thousand dollars per annum.

STRUCK AT LAST.—*Bedrock Democrat*, May 12: Mr. Geo. Cooper, who has put in the major portion of the past two years in running a tunnel to intersect the vein of the Virtue ledge, was in the city yesterday, and informs us that at a distance of 450 feet he struck the coveted prize. The vein at present is fifteen inches in width and exceedingly rich. Mr. Cooper intends to push work on the ledge and get out all the ore possible, the working of which will be done by the Virtue mill, only about one mile distant.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific States.

From the official record of U. S. Patents in Dewey & Co.'s Patent Office Library, 262 Market St., S. F.

FOR WEEK ENDING MAY 11, 1886.

341,539.—DREDGER—H. B. Angell, S. F.
341,725.—CASH AND PARCEL CARRIER—P. Boland, S. F.
341,446.—PAPER CUTTER AND STAMPER—A. Brown, Mendocino, Cal.
341,365.—ELECTRIC GAS LIGHTER—Julius Finck, S. F.
341,566.—AUTOMATIC ELECTRIC GAS LIGHTER—Julius Finck, S. F.
341,572.—TAILORS' OUTLINE MEASURING DEVICE—J. S. Hand, S. F.
341,844.—WEEDING IMPLEMENT—L. C. Hill, Myrtle Creek, Oregon.
341,849.—GATE.—J. Hughesdon, Carlin, Nevada.
341,484.—IRONING MACHINE—J. F. Jacques, S. F.
341,813.—DRILL MACHINE—J. C. Muirhead, Grub Gulch, Cal.
341,691.—STEAM ENGINE VALVE—John Richards, S. F.
341,863.—AMALGAMATOR—J. W. Van Brocklin, Seattle, W. T.

NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates and in the shortest possible time.

Mining Share Market.

There has been no very great amount of animation in the stock market, though a fair business has been transacted at somewhat lower prices than last week. Hale and Norcross is fast approaching the Savage south line on the 2900 level, and the Savage Company itself has put a force of men to work on the 600 level of the Gould and Curry, running south into the Savage mine. This is a really important move, as the drift commences in low-grade ore, and must, it is thought, pass through something much better before reaching the main Savage shaft. No further progress has been made in draining the water in the Osbiston shaft since last week's report, but the tank and station at the 2232 level being about completed, the reduction of the water below that point will be resumed on Monday next. The low-grade ore bonanzas of both the south and north ends of the great lode continue their regular daily output, keeping several hundred men and numerous mills at work; but there is no new feature of interest to record at any point, either in low-grade ore, low-grade explorations, or high-grade hopes.

Bullion Shipments.

We quote shipments since our last, and shall be pleased to receive further reports:

Argus, May 15, \$21,247; Mt. Diablo, 15, \$9987; Alice, 13, \$22,496; Oro Grande mill, 16, \$2350; Hollberg & Thede, 16, \$2450; Hanauer, 11, \$8950; Alice, 11, \$14,263; Hanauer, 13, \$5550; Germania, 13, \$2331; Hanauer, 14, \$7150; Germania, 14, \$2223; Nevada, 16, \$1810; Hanauer, 16, \$2250; Overland, 16, \$1580; Germania, 16, \$6696; Alice, 17, \$11,523. For week ending May 12th, Wells, Fargo & Co., of Salt Lake, received in bullion \$56,130; McCormack & Co., \$68,526; T. R. Jones & Co., \$38,419; Union National Bank, \$27,400; a total of \$190,476.

New York Metal Market.

Telegraphic advices dated May 20th, give the following New York prices:

BORAX—6½¢ @ 7½¢.
BAR SILVER—\$98 per oz.
COPPER—LAKE—\$11.37½.
IRON—No. 1, \$17@18.50; No. 2, \$16@16.50.
LEAD—\$4.85@4.95.
QUICKSILVER—43¢@43½¢ @ lb.
The following is the latest from the "New York Metal Market Report":
COPPER—Quiet; Lake offered at 11.00c. Transferable Notices (Lake) offered at 11.20c. Transferable Notices (Chili Bars) offered at 11.40 15c.
LEAD—Steady at 4.65@4.80c. Transferable Notices (Domestic) issued at 4.85.
SPELTER—Steady at 4.45@4.65c. Transferable Notices (Domestic) issued at 4.60c.
TIN—More active at 20.80@20.85c. Transferable Notices issued at 20.75c.
TIN PLATE—Dull. Transferable Notices issued at 24.35.
IRON CERTIFICATES—Nominally \$18½ asked. Transferable notices (May delivery) issued at \$17.
SILVER—New York, 98 per oz. London, 45d.
MAKER'S PRICES—At tidewater. 100 ton lots of listed irons (when brand is specified) range nominally about as follows: Lehigh, Grade No. 1, \$18@19.50; No. 2, \$16.50@17.50; Grey Forge, \$15.50@17.00. Hudson River, Grade No. 1, \$18@19; No. 2, \$16.50@17.50; Grey Forge \$15.50@16.50. Southern, Grade No. 1, \$18.50@—; No. 2, \$17@17.50; Grey Forge \$16@17.
Prices generally ruling for metals not regularly dealt in on call at the N. Y. Exchange, covering extremes of buyers' and sellers' views. All prompt delivery.—Australian Tin, May 7th, \$20.90@21.10; Billiton Tin, \$21.00@21.25; Banca Tin, \$21.20@21.35; Baltimore Copper, \$9.90@10.15; Orford Copper, \$9.90@10.15; P. S. C. Copper, \$9.90@10.15; Foreign Lead, \$4.70@4.90; Foreign Spelter, 4¼@4½.

Gardner Spring Governor.

TATUM & BOWEN,

25 to 31 MAIN STREET, SAN FRANCISCO, CAL.

91 to 93 FRONT STREET, PORTLAND, OR.

SOLE AGENTS FOR

GARDNER GOVERNOR COMPANY,

J. S. Mundy's Patent Friction Hoisting Engines.

The Mundy Patent has been sustained in the United States District Court of New York against the Ledgerwood Manufacturing Company, and also in the District Court in the State of New Jersey against Kendall & Roberts for infringement. Therefore all parties are cautioned against making, using, or selling Friction Drums that infringe this patent.

Gardner Governor.

GORDON & MAXWELL COMPY MINING PUMPS.

THE MOST EXTENSIVE PUMPING MACHINE WORKS IN THE UNITED STATES.

MORRIS COUNTY MACHINE and IRON CO. New High-Speed AIR COMPRESSOR.

We have recently furnished the contractors the machinery for La Trinidad (300 tons per day) and Silver Queen (100 tons per day). These mines are located in Mexico and belong to La Trinidad Company, of London. The Process is the Wet Concentration, and the Plants are, without doubt, the most substantial and complete of the kind ever built.

WE MANUFACTURE ENGINES, BOILERS, AND SAW-MILL MACHINERY, and Carry in Stock:

Wood and Iron Working Machinery, Best Belting, Lubricants for Cylinders and General Machinery, Including the Celebrated ALBANY LUBRICATING COMPOUND.

THE ORIGINAL Roller Ore Feeder.

(PATENTED JUNE 24, 1873.)

This form of Ore Feeder is well adapted for its peculiar work.

Manufacturers of the Celebrated "Challenge" Ore Feeders for any character of ores; also "Stanford Improved" Ore Feeders and Tullock's Ore Feeders for dry ores.

Prices furnished upon application to

JOSHUA HENDY MACHINE WORKS,
39 to 51 Fremont St., San Francisco.

KNIGHT'S WATER WHEEL

For Mills, Pumping and Hoisting.

OVER 300 IN USE!

All Estimates Guaranteed.

SEND FOR CIRCULAR.

EDWARD A. RIX & CO.,
Sole Agent,

18 and 20 Fremont Street, San Francisco.

TO MINE OWNERS.

WANTED.—By competent man, a position as assayer or millman; has No. 1 assay outfit. References. Address "M," this office.

ASTRONOMICAL TELESCOPES

With Stands, etc., from \$12 to \$1000 each.

3 inch Achromatic, \$59.

7-inch Astronomical Telescope, \$75.

TYDEMAN,

Astronomical Telescope Maker, Camden, N. J.

THE SCIENTIFIC PORTABLE FORGE

AND

BLACKSMITH HAND BLOWERS.

GUARANTEED

The Lightest Running! The Strongest Blast!
The Most Durable!

ADAPTED TO ALL KINDS OF WORK,

LOSSES PAID, \$6,500,000.00

INSURE

—IN THE—

—THE—

LARGEST PACIFIC COAST COMPANY.

This cut represents our

IMPROVED
HYDRAULIC
MACHINE.

IT DIFFERS FROM THE OLD STYLE IN HAVING ONLY ONE JOINT instead of two. It is of greater capacity and more easily worked and kept in repair. The statement of Mr. Hendy that all styles are infringements on the machines made by him, he knows to be utterly false. All litigation has been in reference to old style two jointed machines, which are superseded by our new style one jointed. The decision of Judge Sawyer, referred to by him, is carried up on appeal to U. S. Supreme Court, with absolute certainty of a reversal in our favor. Send for Circulars and Price List. HOSKIN & CO., Marysville, Cal.

IMPROVED FORM OF HYDRAULIC GIANTS.

The above cut illustrates the IMPROVED FORM OF HYDRAULIC GIANTS, which we manufacture. All similar styles are infringements upon this form, and a judgment stands of record to that effect, under the decision of Judge Sawyer of the U. S. Circuit Court in the matter of Heedy and Fisher vs. R. Hoskio et als.

Prices furnished upon application to

JOSHUA HENDY MACHINE WORKS,

39 to 51 Fremont St., San Francisco, Cal.

THE ROLLER ORE FEEDER

(Patented May 28, 1882.)

This is the best and cheapest Ore Feeder now in use. It has fewer parts, requires less power, is simpler in adjustment than any other. Feeds coarse ore or soft clay alike uniformly, under one or all the stamps in a battery as required.

In the Bunker Hill Mill it has run continuously for two years, never having been out of order or costing a dollar or repairs.

Golden State and Miners' Iron Works.

Sole Manufacturers,

237 First Street, San Francisco, Cal.

JAMES LEFFEL'S Mining Turbine Water Wheel.

These Wheels are designed for all purposes where limited quantities of water and high heads are utilized, and are guaranteed to give more power with less water than any other wheel made. Being placed on horizontal shaft, the power is transmitted direct to shafting by belts, dispensing with gearing.
Estimates furnished on application for wheels specially built and adapted in capacity to suit any particular case.
Further information can be obtained of this form of construction, as well as the ordinary Vertical Turbines for Wooden Penstocks and in Iron Globe Cases, free of cost, by applying to the manufacturers,

THE GIANT POWDER COMPANY

Manufacture Three Kinds of Powder, which are acknowledged by all the Great Chemists of the World as

The Safest and Strongest High Explosives in the Market.

GIANT POWDER or DYNAMITE,

Of Different Strengths as Required.

NOBEL'S EXPLOSIVE GELATINE," which contains 94 per cent of Nitro-Glycerine, and GELATINE-DYNAMITE, Stronger than Dynamite and even Safer in Handling.

JUDSON POWDER IMPROVED.

FOR RAILROADS AND LAND CLEARING. Is from three to four times stronger than ordinary Blasting Powder, and is used by all the Railroads and Gravel Claims, as it breaks more ground, pulverizes better and saves time and money. It is as dry as the ordinary Blasting Powder and runs as freely.

BANDMANN, NIELSEN & CO.,

CAPS and FUSE for Sale.

GENERAL AGENTS, SAN FRANCISCO, CAL.

ADAMANTINE. Shoes, Dies and Crusher Plates

We manufacture the above Adamantine Shoes, Dies and Crusher Plates. They are in use on the hardest quartz in the United States and South and Central America, and have been

ADAMANTINE. for the last ten years; we warrant them to outwear three (3) sets made of any other metal, and many report that they last from 4 to 8 times longer than any other make. They never break AT THE SHANK, and the wear is so light that little or no foreign matter gets mixed with the crushed ore.

Also CHROME CAST STEEL for Mining and General Use, of the finest quality.

For further particulars, address

CALIFORNIA

ARTIFICIAL STONE PAVING CO.

(SCHILLINGER'S PATENT.)

—FOR—

SIDEWALKS, GARDEN WALKS, CORRIDORS, OFFICES, CARRIAGE DRIVES, STABLES and CELLAR FLOORS, KITCHENS, Etc.

The Courts here and in the East have decided that Artificial Stone Pavements with plastic concrete and in detached blocks, are infringements on the Schillinger Patent; and also, that when the plastic material is blocked off with a trowel and out through far enough to control the cracking caused by shrinkage, that such pavement is in law the same as if laid in detached blocks, and is an infringement of the patent. All property-owners having such pavements laid without the license of the above Company, will be prosecuted.

PATENT LIFE-SAVING RESPIRATOR

Entirely Prevents Lead Poisoning and Salivation

The most perfect appliance for people engaged in Smelting, Dry Crushing, Gumbo Works, Quicksilver Mines, Lead Corroding, and all other occupations where there is dust, poisonous vapor, or bad odor.

In Feeding Threshing Machines, and similar work, they are indispensable, as no foreign substances can be inhaled when they are worn.

The Respirators are sold subject to approval after trial, and if not satisfactory the price will be refunded. Price, \$3.00 each or \$30.00 per dozen. Sent post-paid to any address on receipt of price.

Address communications and orders to

HOOD'S FOUNDRY COKE.

Consumers are respectfully informed that owing to inferior brands of Coke having been sold in this and other countries under the name of "Patent Coke," the Glamorgan Coal Co. (Limited), Cardiff, in May, 1884, abandoned the title of "Patent Foundry Coke," substituting that of "Hood's Foundry Coke."

This Coke is exclusively used by the Selby Smelting and Lead Co., Union Iron Works, Professor Thomas Price, and other consumers here. Large quantities are regularly forwarded to Copper Smelters in Arizona and New Mexico, and also to consumers in Nevada and Salt Lake.

The undersigned are the SOLE IMPORTERS of the above Coke, which is for sale in quantities to suit purchasers.

\$1,000 CHALLENGE!

**THE FRUE ORE CONCENTRATOR,
OR VANNING MACHINE.**

PRICE: FIVE HUNDRED AND SEVENTY-FIVE DOLLARS.
(\$575 00), F. O. B.

OVER 1,000 ARE NOW IN USE. Saves from 40 to 100 per cent more than any other Concentrator. Concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order and ready to make tests at the Fulton Iron Works, No. 220 Fremont Street, San Francisco.

As the result of a suit East against an End-Shake Machine (the Embrey), similar to the Triumph, the Frue Vanning Machine Company owns the Embrey patent, and can put in the market an End-Shake Machine of earlier patent that will do as good work as the Triumph, and superior in construction and durability. There will be no risk of suit for infringement.

The Frue Vanning Machine Company warn the public that they claim and will prove the Triumph machine to be an infringement on patents owned by them.

Protected by patents: May 4, 1869, Dec. 22, 1874, Sept. 2, 1870, April 27, 1880, March 22, 1881, Feb. 20, 1883, Sept. 18, 1883. Patents applied for.

N. B.—We are and have been ready at any time to make a competitive trial against the Triumph, or any other Concentrator for stakes of \$1,000.

ADAMS & CARTER, Agents Frue Vanning Machine Co.,

Room 7—No. 109 California Street.

SAN FRANCISCO, CAL.

\$1,000 CHALLENGE ACCEPTED, PRICE, FIVE HUNDRED AND FIFTY DOLLARS (\$550.00).

**THE
"TRIUMPH" ORE CONCENTRATOR.**

The present improved form of the celebrated "TRIUMPH" Ore Concentrator possesses many advantages over any other style of Vanners, Vanning Machines, or Concentrators, yet introduced to the notice of mining men. These advantages consist in the superior features which enter into their construction, and facilitate their operation.

They are constructed in the best manner; their frames being of iron, insures their solidity, durability, and perfect steadiness of motion when operated. They are built as compactly as their requisite strength will permit, weigh less, require less freight space in boxes, by which their cost of transportation is reduced, and occupy less mill room when set up.

An important improvement has recently been introduced into their construction, which consists of a RIFLE TABLE, placed in front of and which takes the discharge from the feed and amalgam bowl. The improvement is in the reciprocal motion which is imparted to this table by the longitudinal motion of the shaking frame to which the table is attached. We have at hand many testimonials, from well-known Superintendents of mines in different mining districts of the United States, bearing evidence of the efficiency and superiority of this form of Concentrator, and we shall be pleased to send Circulars covering such letters of testimony, and, as well, directions for setting up and operating these machines, and are ready to quote special prices for any considerable order.

THE JENKINS STANDARD PACKING

IS ACKNOWLEDGED BY USERS AS THE BEST in the world. Unlike all other Packings, the Jenkins Standard Packing can be made any thickness desired in a joint by placing two or as many thicknesses together as desired, and following up joint, it vulcanizes in place and becomes a metal of itself (it is frequently called Jenkins Metal), and will last for years, as it does not rot or burn out. Avoid all imitations, as a good article is always subject to cheap imitations. The genuine has stamped on every sheet "Jenkins Standard Packing," and is for sale by the Trade generally.

MINING MACHINERY.

San Francisco: 127 First Street. Chicago: 100 N. Clinton. New York: 145 Broadway.

PLANTS FOR GOLD AND SILVER MILLS, embracing machinery of LATEST DESIGN and MOST IMPROVED construction. We offer our customers the BEST RESULTS OF 35 YEARS' EXPERIENCE in this SPECIAL LINE of work, and are PREPARED to furnish from SAN FRANCISCO or CHICAGO, the MOST APPROVED character of MINING AND REDUCTION MACHINERY, adapted to all grades of ores and SUPERIOR to that of any other make, at the LOWEST POSSIBLE PRICES.

We are also prepared to CONSTRUCT and DELIVER in COMPLETE RUNNING ORDER, in any locality, MILLS, CONCENTRATION WORKS, WATER JACKET SMELTING FURNACES, HOISTING WORKS, PUMPING MACHINERY, ETC., ETC., of any DESIRED CAPACITY.

WATER JACKET SMELTING FURNACES

For COPPER and ARGENTIFEROUS LEAD ores of NEW and ORIGINAL DESIGNS, covered by LETTERS PATENT. No other Furnace CAN COMPARE with these for DURABILITY, and in CAPACITY for uninterrupted work. MORE THAN 150 of them are now RUNNING in various parts of THIS COUNTRY, as well as many in FOREIGN COUNTRIES, giving results NEVER BEFORE ATTAINED as regards CONTINUOUS running, ECONOMY of fuel, AMOUNT and QUALITY of BULLION produced. These CLAIMS have been PROVEN BY RESULTS in ANY NUMBER of INSTANCES, and the GREAT SUPERIORITY of this SYSTEM of smelting ores DEMONSTRATED BEYOND QUESTION. COMPLETE PLANTS furnished to order of any CAPACITY, with ALL IMPROVEMENTS that experience has DEMONSTRATED as VALUABLE in this class of work.

Beyond question the cheapest and most effective machine of the kind now in use adapted to all grades and classes of ores.

This machine has been THOROUGHLY TESTED for the past TWO YEARS, under a GREAT VARIETY of CONDITIONS, giving most EXTRAORDINARY results FAR IN ADVANCE of anything EVER BEFORE REALIZED. A recent COMPETITIVE TEST at the Carlisle Mine in Mexico, showed an ADVANTAGE OF OVER 30 PER CENT in favor of THE DUNCAN. The amount SAVED OVER THE TRUE being sufficient to PAY THE ENTIRE COST of the machines EVERY MONTH of the YEAR. One of its MOST VALUABLE features is as an AMALGAMATOR. It saves all THE AMALGAM GOLD and SILVER that ESCAPES THE BATTERIES, PANS or SETTLERS, making the machine worth MORE than ITS COST for THIS PURPOSE ALONE.

Baker's Mining Horse Power.

Possessing all the requirements of a first-class hoist and affording means for the continuous operation of a Pump or Blower, without interfering with a hoisting apparatus. It is made entirely of iron, no piece weighs over 300 pounds. At the ordinary speed of a horse, a 1,000-pound bucket of ore may be raised 120 feet per minute. The hoisting-drum is under the complete control of the man of the shaft, and is capable of carrying 500 feet of five-eighths steel rope. SEND FOR CIRCULAR.

SEND FOR CIRCULAR.

IMPORTANT TO GOLD MINERS! SILVER-PLATED AMALGAMATING PLATES FOR SAVING GOLD

IN QUARTZ, GRAVEL AND PLACER MINING.

Warranted the Best Made, Durable and Satisfactory. Full weight of silver and best quality of plating guaranteed.
BEST SOFT LAKE SUPERIOR COPPER USED.

3000 Orders filled. References first class. Prices the very lowest. Have received every Medal awarded on the Pacific Coast for Mining Plates. Old Mining Plates Bought, Replated, or Gold Separated.

SAN FRANCISCO GOLD, SILVER and NICKEL PLATING WORKS, 653 & 655 Mission St., San Francisco.
E. G. DENNISTON, Proprietor.

These Plates can also be procured of JOHN TAYLOR & CO., Dealers in Assayers' and Mining Material, 112 to 118 Pine St.

NOTICE.—Mining men are cautioned against purchasing inferior quality of Silver-Plated Mining Plates now being manufactured in this city. There has been a general complaint by purchasers that these plates proved defective in plating and short in weight of silver, assays showing great deficiency in silver guaranteed. Thin, light plating looks the same as heavy, but has no durability. Good plates can be furnished at same price these poor plates cost.

The Heating Power of Fuels.

The need of new and accurate determinations of the heating value of different coals is well recognized. The recent extensive use of liquid and gaseous fuels, "patent" fuels, tan-bark, and other refuse fuels, also makes a necessity for some correct method of determining the relative value of each of them. The first requisite in determining the heating power of a fuel is proper apparatus, such as has not been used in any of the tests of American coals yet reported. In the hope that more accurate means may be used in future tests, Wm. Kent, M. E., of New York, has called the attention of the American Institute of Mining Engineers to an apparatus which he has designed for the purpose. It is not offered as the best possible apparatus, but contains points of value and may lead to the design of still more suitable devices by others.

In criticising the tests made by Prof. Johnson in 1842, and General Meigs in 1882, Mr. Kent states that they were made by evaporating water into steam in ordinary steam boilers, and says that a steam boiler of ordinary construction is not a good apparatus for determining the heating power of a fuel, for the following reasons:

1. We can have no assurance that the fuel is completely burned. In all coals containing volatile matter, the distilled gases may be chilled by the heating surfaces of the boiler, and escape into the chimney unburned.

2. The heat generated by the fuel is carried away in four different portions: *a*, in the steam which leaves the boiler; *b*, in the "entrained" water which leaves with the steam; *c*, in the waste gases in the chimney; *d*, by radiation from the boiler and brickwork. The relative proportion of heat which disappears in each of these four different ways varies every instant, and the measurement of any one of the portions is an exceedingly difficult matter and liable to great errors.

3. The boiler and furnace having a large heat-absorbing capacity in proportion to the quantity of fuel burned during a test, it is difficult to insure that the conditions at the beginning and end of a test are the same; that is, that in addition to the four outlets for the heat of the fuel above mentioned, a fifth part of the heat has not been absorbed by the boiler and brickwork in making them hotter at the end of the test than at the beginning.

The accompanying illustration is a longitudinal view and section of the proposed apparatus. In this, *A* represents the fire-box; *B*, grate bars; *C*, tubes of upper heater; *D*, lower heater; *E*, connection between heaters; *F*, flue between heaters; *G*, chimney connection; *H*,

chimney; *J*, *K*, water-measuring tanks (closed tops); *L*, waste drain for hot water; *M*, *M*¹, admission valves to tanks; *N*, *N*¹, emptying valves; *O*, *O*¹, overflow and vent pipes; *P*, cold-water supply pipes; *Q*, hot water outlet; *R*, air-supply pipe; *S*, support of upper heater; *T*¹, *T*², thermometers for water; *T*³, *T*⁴, thermometers for air and waste gas; *U*, safety valve.

This apparatus is an attempt to avoid, to a great extent, the sources of error previously mentioned. Its principal feature is that it is not a steam boiler at all, but only a water heater. It consists of two sheet-metal cylinders, each 12 feet long, the upper one four feet in diameter and the lower one three feet, and connected by a short neck at one end only. The upper cylinder is provided with a fire-box 3 feet 6 inches in diameter and 6 feet long, and its rear end is filled with about 100 two-inch

should be calculated from the barometric pressure, and its contained moisture should also be determined. Its temperature should be taken before it enters the ash-pit. The temperature of the escaping gases should be taken by several thermometers, the bulbs of which reach to different portions of the chimney connection. Cold water is supplied to the bottom of the lower heater, at the chimney end, its temperature being taken before it enters, by a thermometer inserted in the pipe. The water supply-pipe may conveniently be attached to the city main. The water passes through the two heaters in an opposite direction to that of the gases of combustion, and escapes at the outlet-pipe at the top of the upper heater by which it is taken to two measuring tanks, which are alternately filled and emptied. The temperature of the outflowing water is taken by a thermometer inserted in the outflow-pipe. The rate of flow of water

plied to the fire. This increase, however, being in any case very slight, and the quantity of air being known, the amount of heat from the fuel which escapes up the chimney can be calculated with but small chances of error.

Arizona and the Indians.

Arizona Territory has been unfortunate in having within her borders the fiercest Indian tribe in the United States. The Apaches have maintained warfare against the whites a great deal longer than was thought possible. When temporarily subdued and brought to the reservation they only waited long enough to make ready for other raids, and wandering hands of them have roamed about the less settled regions of the Territory leaving death and destruction in their path. For many months past a small band of these implacable Indians have defied all

attempts to subjugate them. The rugged character of the country has been in their favor. Moreover, they are able to travel long distances on foot, where troops could not follow on horseback. The United States troops have been at a disadvantage in many ways, and, at all events, have accomplished very little of practical value in settling the Indian difficulty.

General Miles, who has recently assumed command in Arizona, is evidently in earnest in his endeavors to conquer Geronimo and his band. In addition to his troops he has enlisted the services of companies

of Mexican and white citizens. The citizens offer a reward of \$50 each for the Indians or their heads, and \$2000 for Geronimo or his head. Great enthusiasm prevails among the people, who are more hopeful than ever before of a speedy termination of the war.

While the people in the principal towns of the Territory have been perfectly safe, the rapid movements of these predatory bands of Apaches has hindered the settlement of the Territory. Those in small places or isolated camps have been in more or less danger. Prospectors and miners have been prevented from pursuing their avocation in many places. Moreover, capital has hesitated to come to the Territory to develop mines. The presence of the Indians has been very detrimental to its mining interests. Even in those places where there was no danger from Indians it has been difficult to get "outsiders" to come, for they think the Apaches are in every nook and corner. The mining interests of the Territory will never be properly developed until the Indian question is settled forever.

SAN BERNARDINO is now a city, the official document having been signed May 20th.

APPARATUS FOR DETERMINING THE HEATING POWER OF DIFFERENT FUELS

tubes. The lower cylinder is completely filled with two-inch tubes. The fire-box is lined throughout with fire-brick, and contains a grate surface two feet wide by two and a half feet long. A hanging hridge-wall of fire-brick is placed in the upper part of the fire-box, in the rear of the bridge-wall proper, for the double purpose of presenting a hot fire-brick surface to the flame before allowing it to touch the heating surfaces of the tubes and tube sheet, and of changing its direction so as to cause the gases to thoroughly commingle, and thus to insure complete combustion. In testing highly bituminous coals, it might be advisable to have more than one of these hanging walls, and to give the fire-box a greater length, to more certainly insure complete combustion of the gases. The gases of combustion pass through the tubes of the upper heater, then down through a fire-brick connection into the tubes in the lower heater, after leaving which they pass into the chimney.

Air is fed to the fire, under the grate-bars, through a pipe leading from a fan-blower. The air is measured by recording the revolutions of the blower, and the measurement is checked by an anemometer in the air-pipe. Its weight

through the apparatus is regulated, so that the temperature of the outflowing water does not exceed 200° F. The measuring-tanks have closed tops which prevent evaporation, small outlet-pipes being attached to the top of each which serve both as indicators when the tanks are full, and to allow air to escape from the tank when it is being filled with water.

The grate-surface being only five square feet and the heating surface about 1000 square feet, a ratio of 200 to one, or more than five times the usual proportion in a steam boiler, and the water being much colder than that in a steam boiler, the gases of combustion should be cooled down to near the temperature of the air supplied to the fire, especially when, as is usually the case, the water supply is colder than the air. For extremely accurate tests, the water might be cooled before entering by a refrigerating apparatus or by ice.

The whole apparatus being thoroughly protected, by felting, from radiation, the heat generated by the fuel is all measured in the increase of heat given to the water which flows through the apparatus, and in the increase of temperature of the gases of combustion as taken in the chimney, over the temperature of the air sup-

CORRESPONDENCE.

Mining—Its Nobility.

EDITORS PRESS:—Modern civilization is under obligation to the miner. Without the metals there can be no real enlightenment, and the finer the metals the higher the civilization. Take away the metals and man would soon return to barbarism, exactly as he was during the stone age. He cannot advance; he cannot be scientifically refined without using the metals. There is no alternative, no substitute; he must have the iron and steel, silver and gold.

A steam engine won't work made out of glass, nor would a sewing machine be any good made out of rock or wood. The metals make civilization possible. Just think for a moment what man could do if he had no metal for his machine, his engine, his telegraph, telephone, electric light, etc. Why, he couldn't have them, of course. Strike from our possession all metals, and render it impossible to obtain more, and you would soon behold the present race sink to the level of the savage. Man, then, would have no railroad, no ocean steamer—not even a stove to warm him in winter, while he would be compelled to do his plowing with a forked stick and live in a hut or a dugout. I am thankful that nature has furnished the metals so we can find them and use them, and make life worth living.

I hold that the mining industry is a noble and glorious work—that the miner is a benefactor, that his products are permanent and a lasting gift in aiding and helping the whole world. His gold and silver is the vital "life blood" of commerce—it facilitates international intercourse. Every bright dollar represents so much labor—it is, in one sense "omnipotence" limited. That is why so many are after the almighty dollar. Why, I have never met even "a true Christian" who obeys Christ's command—"Sell all thou hast and give to the poor."

It seems they would rather not sell—they like the gold on earth and expect even golden streets in "heaven." Strange, is it not? Let that be as it may; I would prefer that, what little gold there is in this globe be arranged nearer the surface. We are willing to take chances on decent "outcrops" and it makes no difference to us on this globe whether the streets in "heaven" are gold or lead. I would rather have a million in gold here in this world than to walk over golden streets in heaven. The facts are, I don't want to be an angel. But enough—"one world at a time" is what I believe in.

Does mining pay? I rather think if it did not pay there would not be many men engaged in the business; it pays, and it pays big. There has been billions made at mining.

For instance, during the year 1882 the value of the metallic products of the United States alone was more than \$219,756,000 of which \$79,300,000 was in gold and silver. (Fourth Annual Report United States Geological Survey.)

Without full statistics regarding the amount of capital invested and the number of men connected with mining, it would be difficult to give definite figures in regard to the profits of the business. It is known, however, that the profits are very liberal, taken as an average. Of course, it is like any other industry in this respect, and that is, it requires competent men in order to make it a success. Great progress has been made during the last decade. Mining to-day is a science, and modern miners are men of science. They don't "go it blind"—they read the rocks, they unlock the hidden treasures with the veritable key of geology. Before a pick or drill is brought to use on the ground the miner sees what he has on the surface; if the evidence is not complete he doesn't touch it. He takes as few risks as possible. He knows certain indications and his constant experience brings to light new facts. "Facts" are his delight. He is a practical man, and practice makes perfect. Mining, he it remembered, is no child's play; it takes the most proficient workmen to open and develop a great mine. "Skill" or practical ability is the miner's reliance; his confidence is based wholly on facts. Without such dependence, there can be no science.

Modern mining means successful mining. There is no excuse for failure. Ignorance is the cause of the latter. Millions of dollars have been wasted by ignorant men. Why, I know of men who spent months cutting tunnels and sinking shafts through "mountains of granite" looking for coal. They didn't find coal in that rock. It is a geological impossibility for coal beds to exist in archaic or azoic granite. Those "miners," if such they can be called, didn't know the rudiments of geology, hence the failure. There can be no science in mining without a knowledge of geology. The successful miner of the present day is also a practical geologist. Without such knowledge he can be no more than a pretender, as much so as the leaders of the Mormon church. Mining, again, is a perfectly legitimate industry; nobody is robbed; the metal is taken direct from

nature. It is time that this clamor about mining being illegitimate were hissed down.

None but the impostors, dupes and ignoramus hold to such an absurd conception. There are no facts to sustain even the idea of such a thing. The cry may be always traced to those who have been swindled and cheated by the impostors who handle "wildcats." Mining is pre-eminently a legitimate work—perfectly consistent with morality, and, in itself, is a moral work. I challenge any person to show otherwise, and last, but not least, the production of the metals means also scientific progress. "The finer the metal the higher the civilization;" the more steel, silver and gold the better for the whole race, unless barbarism be preferable to enlightenment. I like mining and I like every honest miner. This industry is full of promise throughout the occident, and the western miner has a bright future; there is a ready market somewhere in the world for all the metal he can put on top of the ground. So let us pick and drill and break treasures from the old globe's crust, and let the "illegitimate fiends" grumble and growl until they are sick. All progressive men have faith in mining; they see the need of it. The time approaches when this industry will become ten times its present importance. Mining must continue and the demands of humanity will cause the work to increase rapidly in order to supply the needed metals.

Kaysville, Utah.

Hints For Lubricating.

EDITORS PRESS:—"The time will come when it will be considered a degrading adulteration to mix animal oils with pure petroleum refined lubricants." So said an experienced and distinguished oil manufacturer of Boston, ten years ago. The assertion was based upon the clumsy mechanical mixtures at that time but too common. Since then, products have been reached by the redistillation and super-steam heating of petroleum oils which would startle the conceptions of the Boston veteran, and his prophecy is daily being realized in those great manufacturing centers where closeness of competition has made the most economical choice and use of lubricants a point of necessity.

In the West, however, where all things are done on a more liberal, even if smaller scale, there remains obstinately an adherence to the more costly animal and vegetable oils and the cheaper fish oils, simply because they are traditional.

Imagine the cost to railroads, for example, if, with the immense extensions to which they have grown during the last score of years, they were still compelled to depend for their lubrication on lard-oil.

The writer well remembers his first interview with the master-mechanic of a prominent Eastern railroad twenty years ago. The occasion was the offering of a pure, heavy, natural Ohio oil for the lubrication of the locomotives.

"But it is black!" exclaimed the officer. When a few drops poured on the slides, and then removed with waste, left them bright and shining as before, he no longer considered color an objection, and after a long interview he reluctantly tried ten gallons! In a fortnight he ordered ten barrels; and in two months the oil was in constant use over the entire line. Now, oil of this character has been recognized as standard by all the great trunk lines of the country. Whale-oil, the old R. R. standby, is no longer heard of in the shops or on the road.

Mining and millmen and managers of factories appreciate pure and chemically-blended mineral oils because of their perfect freedom from gum. In all machinery where the multitude of spindles makes the labor of cleaning intolerable and expensive, these oils are deservedly popular. Yet, now and then, the oil-pilgrim encounters engineers and superintendents who will not believe that an oil is good for anything unless they have to spend half an hour after steam is shut off at night removing the coagulated gum from exposed surfaces of friction.

CHARLES J. WOODBURY.

Comparative Trials of Quartz Mills.

EDITORS PRESS:—I observe that there has lately been made at the Oro Plata mine, near Murphy's, in Calaveras county, a competitive trial of a 15-stamp mill and four Tustin barrel-mills, and that the latter gave somewhat better results.

At the usual rate of duty of a stamp-mill, that is, one and one-half tons per day of hard quartz to the stamp, this gives for the 15 stamp mill 22½ tons per day, and as the four Tustin mills are said to have done somewhat better work, their duty may be placed at 24 tons per day, or six tons to each mill.

I would call, for purpose of comparison, the attention of your readers to a quartz-mill lately introduced on this coast, and noticed in your issue of the 15th of this month, and which is now in operation at the Pacific Iron Works in San Francisco. I refer to the Frisbee-Lucop mill, the principle of which was demonstrated to my satisfaction, after many practical trials

on a large scale, to be correct, and the results superior to any mill as to efficiency and economy of work. The principle involves the pressure, by centrifugal force of steel rollers, driven by a driver, running at a high speed against a ring-die of chrome crucible steel.

These mills are of different sizes, and we will take the size having a diameter of 20 inches. Its weight is but 3500 pounds, complete, that often mortars alone of the stamp-mill spoken of (15 stamps and 3 mortars) will reach at least 9000 pounds, and light at that, for mortars in many mills weigh 3500 to 4000 pounds each. The 4 Tustin mills weigh as much. Compare these weights with that of the Frisbee-Lucop mill, complete (3500 pounds). Weight means cost.

We will proceed next to comparative horsepower required. The 15-stamp mill requires about 20-horse power; the 4 Tustin mills a little less power, and the 20 inch Frisbee-Lucop mill about 8-horse power.

The next, and equally or more, important point is the comparative capacity of these three radically different forms of mills, each being best of its kind. The 15-stamp mill, per day of 24 hours, will reduce 22½ tons; the 4 Tustin mills, together, about 24 tons in the same time; and the single 20-inch Frisbee-Lucop crushes at the rate of 24 tons, and this result has been obtained with them in constant operation on hard quartz and other material in the East during the past year. The operation has been under the supervision of Pacific Coast men, who, by practical experience, have become thoroughly skillful in quartz milling. I have recently received statements from these gentlemen, who are entirely reliable, showing this duty done, though it seems almost incredible that so small a machine as that, the ring-die of which is only 20 inches in diameter and face of die 3 inches, can do such great work. The wear of these mills is only 1 cent per ton crushed.

Comment on the above figures and facts is scarcely necessary to the intelligent, practical millman, and their importance to the mining interests of the Pacific Coast cannot be overestimated.

I have proposed to Mr. Gideon Frisbee, the general manager of the "Frisbee-Lucop Mill Co.," and who is now in San Francisco, to place one of these mills, preferably the largest size (24 inches in diameter), in some first-class stamp-mill for prolonged comparative trial, and should such trial be made, and I have every reason to believe it will be, record will be kept of the results for future reference and publication in the PRESS.

Sonora, Tuolumne Co.

Quartz-Crushing Machines.

A Hint to the State University.

Which crushing machine shall I buy? This question every man who is about to erect quartz machinery, and wishes to do the best for himself or his company, is forced to ask himself. So far the answer is, nine times out of ten, in favor of stamps; but it does seem strange that in such a brilliant age as ours no improvement can be made on the primitive stamp. The efforts of inventors have produced a large number of grinders and crushers involving all sorts of mechanical movements, about which the public know absolutely nothing, and no one now feels able or willing to go to the expense of giving any of these machines a trial. We counted in the advertising columns of an Eastern paper no less than 12 machines for grinding quartz "or other hard substances to a powder," and each of these machines is fully warranted to do just what is advertised. Now, none of these machines are anything like as expensive as a battery, and all may be had of any desired capacity. Cost is the problem that stares the owner of a quartz mine in the face when he begins to think of a mill, and the cold chills run down his back as he gazes on the figures resulting from his investigations.

Now, we beg leave to ask our State University solons if it is not possible, amid all the experiments they are continually carrying on in the interest of the honest Granger, they can do a little for the honest miner? We think it would be a grand idea for the School of Mines connected with the University to undertake to test the various machines now offered for the grinding of quartz, in order to furnish the miner with accurate information as to their value. We have no doubt that the inventors of these new appliances would gladly furnish the machines and every facility in their power for making the experiments, for whoever came out victorious would have scored a big point. The test should also include the fitness of the ores for amalgamation after grinding, for in the various means used to accomplish this, the ore may be made better or worse for saving the gold contained therein.—*Sierra Tribune*.

MEDAL AWARDED.—The Board of Judges appointed by the Franklin Institute, after an exhaustive examination of the state of the art, have recommended the "Grand medal of honor" in favor of Thaddeus S. C. Low of Norristown, Penn., for his substantial improvement in the manufacture of water gas, and for his numerous improvements in methods and appliances for utilization of water gas as a fuel for domestic and industrial purposes, and as an illuminating agent.

MINERS are warned at Victoria, B. C., not to go to the Granite Creek mines.

Copper in Boiler Construction.

Many materials have been used at different times in the construction of steam boilers. Thus boiler shells have been made of wooden staves, of granite, of copper and of cast iron, while for the interior portions in contact with the fuel or with the heated products of combustion cast iron, copper, brass, wrought iron and mild steel have all been and still are employed. The use of copper for these interior portions, remarks the *Mechanical World*, and to some extent for the outer shells, was formerly somewhat common, and more especially for marine boilers, where salt water had to be used. But within the last quarter of a century it has been to a large extent superseded by iron or steel, so that one hardly hears nowadays of copper being used in this connection except for small domestic boilers, pot boilers used in certain trades, and for the fire-boxes and sometimes the tubes of locomotives. The reasons for this change of practice are not far to seek. Although copper does not ordinarily rust to anything like the same extent as iron, it is somewhat more rapidly damaged in the furnace by the use of sulphurous fuel such as engineers are often obliged to burn. Again, when from any cause a leak is sprung in a joint, it is not so readily taken up or calked as is the case with iron, and, furthermore, any incrustation from salt is found to deteriorate the metal in the vicinity of the leakages to a greater extent. Then, too, copper is sooner reduced in tenacity by accidental over-heating. Iron does not become perceptibly weaker up to a temperature of 570°; after that temperature is reached the strength gradually decreases, whereas copper is in its best case when cold, and loses tenacity by every increase of temperature. Stated in even numbers the strengths of the three kinds of material now most used, stand to each other about as follows:

Mild Steel.....	97,000
Good wrought iron.....	50,000
Tough copper.....	34,000
Do. at 570 deg., about.....	27,000

Add to the above disadvantages the greater first cost of copper (very much reduced within the past few years, but still considerably more than steel or iron), and it is not surprising that its use is now so much limited.

Yet with all these disadvantages it has some important advantages over both the other materials mentioned. It is far less liable to blister than is iron; it is much more to be relied upon than mild steel, which has often proved itself very treacherous; it can be made and repaired with much less labor and cost than either iron or steel. It has a much higher conductivity, and so is less liable to injury from overheating; it is not so readily incrustated by the use of foul water, and, finally, the value of the scrap copper from an old boiler is considerable as compared with its first cost, while that of a worn-out steel or iron boiler is inconceivable. It seems, therefore, that a good case may be made out for its more extended use now that the first cost is so immensely reduced, in spite of its comparatively low tensile strength and in the face of the high pressures now generally used. As bearing on this point it must not be forgotten that the fire-boxes of locomotives, which have to stand very high pressures and very intense heat, are still, except in this country, where mild steel is largely employed, almost universally made of copper, and even here there are many advocates for the use of copper.

One reason advanced for the adoption of steel in place of copper in the United States is of a somewhat special nature. The fuel used is anthracite, and this, from its hardness and the sharpness of its fractures, is found to injure copper fire-boxes mechanically. The greater hardness of the steel employed mitigates this evil. Mr. Ternie, in his paper read last year to the Institution of Civil Engineers, mentions as one reason for employing steel in place of copper in the locomotives of the Pennsylvania railroad that it better resists the intense heat developed by the blast acting on the anthracite coal. But this, adds our exchange, must surely be a mistake, as the well-known greater conductivity of copper is all in its favor in this respect. Should the many advantages (including lower price) enumerated above lead to an extended use of copper as a material for the construction of steam boilers to work at high pressures, no doubt efficient strength will be obtained, either by increasing the number of internal stays or by varying the forms, or by a combination of these methods. The difficulties in this direction are by no means insuperable, and there would appear to be room for a largely extended use of copper in this as in many other directions.

A SLOKENS SUIT.—The suit of Acter Hardt against the Liberty Hill Consolidated Mining Company is pending in the United States Circuit Court. Hardt sues to prevent the defendant from carrying on hydraulic mining, and on his motion Judge Sawyer granted a temporary injunction, preventing the defendant from mining until the suit is decided. A motion of the defendant to modify the temporary injunction was denied by Judge Sawyer.

The second oil well at Puente is a success at a depth of 300 feet. A fine body of oil is produced, of rather heavy quality, but excellent for fuel purposes.

Honduras Mines.

More or less attention has of late been directed to Honduras by reason of reports announcing the discovery of rich gold fields. Honduras is a State of Central America, extending east and west from the Caribbean sea to the Pacific ocean, and separating Nicaragua on the south-east from Guatemala on the northeast. It stretches in north latitude between 13° 10' and 16°, and in west longitude between 83° and 89° 45', containing about 47,000 square miles. The country is generally mountainous, being traversed by the Cordilleras, which connect the Andes on the south and the Sierra Madre on the north. The minerals known to be found there are, gold, silver, copper, iron, cinabar, zinc, antimony, iron, platinum, asbestos and coal. Mining was formerly the chief business of this country, but has been more or less abandoned. The difficulties of transportation are great. There are very few working mines, and the native laborers only get 50 cents per day. Rich places to work by hand are scarce, and although there are large tracts of mineral land, the country is no place for a poor man. The account of the placer deposits on the Guayape river are now said to have been greatly exaggerated. All accounts agree, however, that poor men have no business to go there.

A Honduras correspondent of the *Engineering and Mining Journal* writes a letter in which he warns men from coming to that country, unless they are well provided with money. He states that in two trips to Olanchito and the Guayape river, while he did not find them barren of gold, he saw nothing to cause a "rush." For two hundred years the Spaniards and natives have been washing gold in the Guayape river, which runs through the Department of Olanchito. They have washed with a "batea," doing a little sluicing, and feeling satisfied if they got twenty-five cents a day. Women are now washing there who are glad to get \$2 a month for their labor. This correspondent does not believe there is a rich place accessible where a poor man could make wages washing, and sincerely trusts that no man, who is not abundantly able to buy a mule or two and keep himself for six months, should come to Honduras. The following paragraphs from the letter referred to give just the information miners want:

A man coming here via Puerto Cortes, which is the nearest port to the gold fields, must travel eight days by mule till he reaches Olanchito, and when he gets there he will not find gold all ready to wash out in a pan, a cradle, or even a sluice. The natives are not savage, and many of them can beat the best American miner in panning and in the use of mercury, and their knowledge of ores and minerals is wonderful.

You can get no outfit in Honduras, but must buy pans, shovels, picks, steel, hammers, explosives, fuse, blankets, tents, saddles, and, in fact, everything in New Orleans. At Puerto Cortes you take the railroad to San Pedro, where mules are taken to Olanchito. Bring your United States bills with you and the merchants will give you about 33½ per cent premium.

Cargo mules are worth \$60; saddle mules, from \$100 to \$200.

In traveling over the country, it is not necessary to pack many provisions with you. There are many ranches and pueblos where corn, tortillas, beans, eggs, chickens, coffee, sugar, dried beef, etc., can be had. Flour, there is none, consequently cakes made of ground-up corn are used as bread.

New Orleans to Puerto Cortes, \$30; Puerto Cortes to San Pedro, \$3, by the railroad; by the steamboat that goes from Puerto Cortes up the Ulua river to Rio Pelo, \$4. Rio Pelo is one day's journey from San Pedro, and for men with plenty of stuff it is better to take the boat that connects with every alternate steamer at the port.

Men who intend to walk, unless they know exactly where they are going, had better stay at home. Tramping in the cool mountains of Colorado is very different from going through the coast swamps and hot tablelands of the interior. Orancho is clear from underbrush and comparatively easy to prospect. Finally, let me urge most seriously upon you the idea that none but men with a good "stake" should come to Honduras. Miners cannot compete in the few working mines with natives, at 50 cents a day. They cannot find rich places to work by hand. They will suffer privations, get the fever, and, perhaps, die.

Tunnel Projects.

The Big Bend tunnel project, recently described in the *Press*, and which lays bare some 14 miles of the suriferous bed of the Feather river, is an enterprise of more magnitude than ordinary mining companies care to undertake. But if the scheme is successful, as hoped, similar enterprises will doubtless be carried out. This river mining experiment is being watched with great interest by miners all over the State. All the branches of the Feather river contain more or less gold, and other tunnels will be run to drain portions of the bed if the Big Bend Company makes good cleanups after the river water is turned into their tunnel. The anti-debris people can find no objection to such projects, as no material is put into the river.

Another big tunnel project for the development of quartz mining interest is also proposed, this time in Nevada county, in this State. This is the Gold tunnel mining scheme, and it is expected that work on the tunnel will be commenced in the next sixty days. The main tunnel as projected will extend from just above Hoyt's crossing, on the South Yuba river, to the vicinity of Town Talk, on Gold Flat, a distance of a little more than four and a half miles, following the Wyoming, Ural and Providence lodes. One branch will pass through the Gold Flat district, and another branch will tap the Idaho and neighboring claims. The total length of the main tunnel and branches will approximate eight miles.

The Nevada Transcript says of this scheme: In the region which it is proposed to penetrate by the tunnel are known to be 120 gold-bearing ledges, and from them it is estimated upward of \$100,000,000 worth of gold has been extracted during the past 35 years.

The workings have, as a rule, been superficial, a depth of more than 300 feet having been attained in but two or three places.

It is calculated that at a point 3000 feet from the mouth of the tunnel a vertical depth of 812 feet will be attained. The vertical depth at the Newtown road, near Mrs. Pooler's place, will be 1222 feet; at Gold Flat it will be 1600 feet, giving backs on the ledges of from 2800 to 3000 feet; and at the Idaho the tunnel will bottom the present workings at a vertical depth of something like 1250 feet.

The tunnel, if completed, will give perfect drainage to the entire mineral belt mentioned, and permit of the cheap working of the ledges.

Educate the Mind as well as the Hand.

Every man who is engaged in any kind of mechanical labor should cultivate studious and observant habits. There is scarcely any description of knowledge but which he will at some time have use for, especially if he ever hopes to rise above the position of ordinary mechanical labor. No man can ever hope to attain distinction as a mechanic unless he educates his mind as well as his hands.

One of the most important acquirements of a mechanic is that he should be able to readily and lucidly convey ideas to another. Many men, says a contemporary, otherwise competent to direct others have failed from lack of this faculty, or have refused good positions because they knew their weakness in this respect. Perhaps as many foremen fail from this cause as from any other. Undoubtedly, this faculty is one to be acquired; it is not one, if there are such, that is born with a man. Every man who works at a mechanical business should labor in the direction of acquiring the habit of concisely expressing his ideas, making this a part of his mechanical education. Talking of such subjects will help a man; writing of them is excellent practice.

A Good Mechanical Eye

Is also a most essential requisite in a good mechanic. No one can ever attain distinction as a mechanic unless he is able to detect ordinary imperfections at sight, so that he can see if things are out of plumb, out of level, out of square and out of proper shape, and unless he can also detect disproportioned or ill-shaped patterns. This is a great mechanical attainment, and one which can be readily attained by any ordinary person. Of course, there are defective eyes as there are other defective organs; the speech, for instance, is sometimes defective, but the eye is susceptible of the same training as any other organ. The muscles, the voice, the sense of hearing, all require training. Consider how the artist must train the organ of sight in order to detect the slightest imperfection in shade, color, proportion, shape, expression, etc. Not one blacksmith in five ever attains the art

of hammering square, yet it is very essential in his occupation. It is simply because he allows himself to get into a careless habit; a little training and care is all that is necessary for success.

The fact is, says the writer, that the eye is not half as much at fault as the heedless mind. Some carpenters acquire the careless habit of using a try-square every time they plane off a shaving, in place of giving their minds right to their business and properly training their eyes, and unless they cultivate this power of the eye they will always be at journey work. Look at the well-trained blacksmith; he goes across the shop, picks up the horse's foot, takes a squint, returns to his anvil, forges the shoe, and it exactly fits the foot. Contrast him with the bungler who looks at the foot, then forges a shoe, then fits the foot to it, often to the ruin of a fine horse. Now, this fault lies in ever allowing himself to put a shoe on that is not in proper shape for the foot; he should determine to make the shoe fit the foot in place of the foot fitting the shoe, and he should follow it up until the object is accomplished.

How to Train the Eye.

A very good way to discipline the mechanical eye is to first measure an inch with the eye, then prove it with the rule, then measure a half inch, then an eighth, and so on, and you will soon be able to discover at a glance the difference between a twelfth and a sixteenth of an inch; then go to 3 inches, 6, 12, and so on. Some call this guessing; there is no guess work about it. It is measuring with the eye and mind. Acquire the habit of criticizing for imperfections every piece of work that you see; do everything as nearly as you can without measuring (or spoiling it), or as nearly as you can trust the eye with its present training. If you cannot see things mechanically, do not blame the eye for it; it is no more to blame than the mouth is because we cannot read, or the fingers because we cannot write. A person may write a very good hand with the eyes closed, the mind, of course, directing the fingers. The eye is necessary, however, to detect imperfections. Every occupation in life requires a mechanically trained eye, and we should realize, more than we do, the great importance of properly training that organ.

Wool Manufacturing.

In cotton manufacturing there has been from the first a decided tendency to the concentration of capital at comparatively few points, and generally in few hands. The business has usually been conducted in large establishments. Cotton manufacture has been the chief factor in building up such large cities as Lowell, Fall River, etc. On the contrary, wool manufacturing has exhibited a much less inclination to centralize. The bulk of the woolen mills of New England are scattered up and down her valleys everywhere, dependent for power upon her numerous streams, and affording a convenient and remunerative market for her local product of wool. Woolen manufacture has never been an important factor in building up any large town in this country. The introduction of the power loom and small factories is simply carrying out its early form as a "household industry" on a larger scale, and on something of a co-operative plan.

The reason for this difference in the two industries is, no doubt, due to the double fact that the prosecution of the latter is less complicated, and that it had already proved remunerative, even as a household industry, a result which cannot be expected of cotton. It is for this reason that a period of depression in the woolen industry makes a comparatively less stir in the industrial world than a similar depression in cotton manufacture. A few thousand operatives thrown out of employment in such a city as Fall River creates more comment and stir than double that number discharged from employment in a dozen different localities. Small bodies of sufferers scattered through small county towns will be more readily absorbed into other industries, than a large body in a town chiefly devoted to a single industry.

For reasons which will be naturally inferred from the above, the woolen industry is the one of all textile manufactures which should be especially encouraged in California. The history of the introduction and progress of the industry thus far on the Pacific coast is similar in character with that above outlined for the Atlantic coast. Its introduction both there and here has met with a larger degree of success than almost any other which can be undertaken on a small scale and with comparatively little capital. Every large town on this coast, whether supported by mining or agriculture should have its woolen mill. It is an industry which always pays under good management.

CALL FOR CHROME IRON ORE WORKS.—The San Luis Obispo Mirror says: "Quite a quantity of chrome ore litters the yard of the railway company awaiting shipment. It is a wonder, at least to us, why some enterprising parties do not erect a refinery here for this ore. It is to be found in almost inexhaustible quantities in the county, and if it pays to ship the ore in a crude state to Baltimore, it would certainly be as profitable, if not more so, to refine the ore here."

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

CASH AND PARCEL CARRIER.—Patrick Boland, S. F. No. 341,725. Dated May 11, 1886. This cash and parcel carrier is intended for service in stores. It consists of a peculiarly-arranged guard or latch, by which the supporting wheels of the device are prevented from leaving the rope or wire track. In the construction of this particular class of apparatus, two deeply-grooved rollers or pulleys are journeued upon a frame, one in front of the other, and the parcel-carrying basket is suspended from the lower part of the frame. The wire upon which the apparatus travels has one end attached at the receiving desk and the other is connected with a vertical post at the counter end, so that it may be raised or lowered to change the inclination and cause the car to run either to or from the desk or counter. At the counter end the car runs from the wire into the height of a rope or cord, which is so arranged that the car and basket may be lowered to a point within reach of the salesman. This end of the wire is supported by an arm, or trap, which is bent sufficiently to one side to allow the carriage to pass by it upon leaving the wire and on to the rope. In order to allow the car to pass the trap it is necessary to have the fixed guard or lower part of the frame, which is curved around beneath the pulleys, left open upon one side sufficiently to allow the bent arm to pass between this guard and the pulleys, and from this cause there is danger that the car will leave the wire and fall off. In order to prevent this, spring-arms or gates have been connected with the frame. Mr. Boland provides a peculiar bent arm, which overcomes the present difficulties, forming a guard, without springs, and through which it is impossible for the rope to escape.

DREDGER.—Horace B. Angell, San Francisco. No. 341,539. Dated, May 11, 1886. This dredging or excavating apparatus consists mainly of an excavating drum or cylinder with suitable driving mechanism by which it is rotated, a stationary suction tube or pipe in suitable relation with the excavating drum to receive the material and engine by which the excavator is driven, an inclined ladder hinged to one end of a float or dredge-boat, and supporting these devices, and a means for connecting this movable mechanism with the stationary boilers and pumping apparatus on the boat. For dredging or excavating, various devices are employed, among which is an endless chain of buckets moving over an inclined ladder or frame, one end of which is hinged to a boat, upon which suitable driving machinery is placed, while the other sinks to the bottom or rests upon the spot to be excavated, so that each bucket may be filled as it reaches the bottom and pass up the inclined ladder to be discharged at the top. Another form consists of a rotary digger driven by a central shaft and having a vertical telescopic tube extending upward from it to a pump, by which the excavated material is drawn up to the surface, the telescopic pipe allowing the cutter or excavator to work at different depths. In this invention, Mr. Angell has combined an excavating-drum rotating upon its own axis with an inclined supporting-frame or ladder hinged at its upper end to a dredge boat, and having a suction pipe of fixed length supported upon it and leading from the excavator to a pump and discharge. This admits of moving the excavating-cutter on a vertical arc about the trunnions of the ladder, while the side movement is obtained by swinging the dredge boat about suitable speeds or anchors.

ELECTRIC GAS-LIGHTING APPARATUS.—Julius Finck, San Francisco, assignor to Will & Finck. No. 341,565. Dated, May 11, 1886. The object of this invention is, first, to provide an apparatus in which a battery of light power can be used for generating the spark, this being rendered possible by the fact that the spark-circuit remains open normally, and is only closed at the moment of use. A further object is to provide a means for opening or cutting out both the spark and the supplementary circuit, when, by reason of any derangement in the mechanism, they remain closed; to provide an alarm to give notice of such opening and its cause, and to furnish a means by which the circuits can be returned to their original condition after the cause has been removed.

AUTOMATIC ELECTRIC GASLIGHTER.—Julius Finck, S. F., assignor to Will & Finck. No. 341,566. Dated May 11, 1886. The object of this invention is to provide electrical apparatus, by which any number of fixtures, with any number of burners, in the same or separate rooms, may be simultaneously or independently lighted.

THE YUKON MINES.—The steamer *Leo* has reached Port Townsend from Sitka. Trouble is apprehended with the Indians at Chilkat over the control of the business of package. Other Indians offering to do the work cheaper. Several new fishing stations have been started along the coast. Miners are still rushing in droves toward the Yukon country, of whose richness incredible stories are told.

TABLE OF CONTENTS.

ILLUSTRATIONS.—Apparatus for Determining the Heating Power of Different Fuels, 353. Section Across Mt. Morgan, with Cup-Deposit of Geysers; Gresham's Patent Automatic Re-Starting Injector, 457.

EDITORIALS.—The Heating Power of Fuels; Arizona and the Indians, 353. Passing Events; Gold Quartz Mines; Alaska Mines; Nominal Capital and Market Value; California Clays; Foundry Notes, 356. Working Gold-Bearing Sulphurets; Automatic Re-Starting Injectors; A Curious Gold Mine—No. 2; Mining Accidents, 357.

CORRESPONDENCE.—Mining—Its Nobility; Hints for Lubricating; Comparative Trials of Quartz Mills, 354.

MECHANICAL PROGRESS.—Slow Power and Friction; Fracture from Centrifugal Force; Steam Gauges not Infallible; Compound Engines; To Temper Tools; A New and Useful Alloy, 358.

SCIENTIFIC PROGRESS.—Density of the Sun; How Sap Flows; A Strain Indicator for Use at Sea; The Health-Giving Properties of Rain; A Newly-Discovered and Newly-Formed Lake; Notes on Cast Iron; The Movement of Glaciers; A New Thermo-Chemical Battery; Influence of the Moon on a Magnetized Needle; Origin of Sulphur in Coal; The Reproduction of Electricity; Origin of Nitrogen in Soils, 353.

ENGINEERING NOTES.—The Panama Canal; The Telegraph in China; Engineering at Cambridge University; Connecting the Hudson with Lake Champlain, 359.

USEFUL INFORMATION.—Fire-Proof Buildings; Registering the Speed of Railway Trains; Telephone Wires Soon Wear Out; Fire Crackers; Red Watch Hands; Rats Eating Putty and Paint; Car Horses; Bird Oil; An Amusing Experiment; To Soften Wrought Iron, 359.

GOOD HEALTH.—Our Sleeping-Rooms; How to Brush the Teeth; Salicylic Acid Suet; The Mind and the Legs; Care of the Hands; No Warmth in Clothes, 359.

MISCELLANEOUS.—Quartz-Crushing Machines; Copper in Boiler Construction, 354. Honduras Mines; Tunnel Projects; Educate the Mind as well as the Hand; Wool Manufacturing; Notices of Recent Patents, 355.

MINING SUMMARY.—From the various counties of California, Nevada, Arizona, Montana, Idaho, Utah, Colorado, Oregon, Washington, New Mexico, 360-61. **MINING STOCK MARKET.**—Sales at the San Francisco Stock Board, Notices of Meetings, Assessments, Dividends, and Bullion Shipments, 364.

Passing Events.

The burning of the hoisting works and destruction of the fine pumping plant of the Grand Central mine, which occurred this week, is a severe blow to Tombstone, Arizona. The camp can ill afford such an accident at this time.

The starting up of the new mill at Candelaria, Nev., is a great event for Columbus district, and the miners expect a renewal of prosperity in that region.

There are rumors that one of the principal mines in Sierra county, near the Nevada county line, has been sold for a good round sum in the London market. If this proves true, the region thereabouts will be greatly benefited, as the mines near by will have an increased valuation.

There is some excitement in the neighborhood of Susanville in the Honey Lake country, Nevada, over the new gold workings south of that town; both placer and quartz mining is being prosecuted with encouraging success.

All the furniture manufactories in St. Louis are closed, owing to the attempt of the proprietors to return to the 10-hour system.

Gold Quartz Mines.

The gold quartz mining industry of this State was never in better condition than it is to-day. There is less excitement and "boom" and more work than formerly. All over California quartz mines are being opened and developed, and those who have good properties have no difficulty at all in disposing of them to advantage, if they choose to sell. In fact, this demand for developed, paying mines greatly exceeds the supply. Of course there are many "prospects" not yet proven to be mines which are for sale, and do not sell so readily as the owners could wish; but once they are opened sufficiently to become real mines, purchasers may be found.

It is pleasant to know, moreover, that there is more probability of this demand increasing than falling off. The reasons are not far to seek. Silver is quoted at lower prices than ever before; copper is also low; and lead quotations have been unsatisfactory to producers for several years. Men who have been mining for those metals are turning their attention to gold. California is the largest gold-producing region in the United States, and, notwithstanding the various "set-backs" to mining here of late years, the annual product remains about the same.

The restrictions placed by the law on hydraulic mining have caused the miners in this State who formerly engaged in that branch to turn their attention to drift and quartz mines. Many mines abandoned for years have been reopened, and old regions have been reprospected with gratifying results. In some districts old gold mines have been started up by men of means and proved profitable in their hands, which they did not when owned by poor miners.

The fact that some of the deepest gold mines in the State are to-day paying handsomely is encouraging to those who are working in gold quartz. When "pay ore" goes down the mine is bound to pay for a long time. Ore can be worked to-day for less than half its cost 15 or 20 years ago. Provisions and labor are cheap, sources of supply are convenient, means of transportation are at hand, and the climate is favorable for steady work. With these advantages it is no wonder that our quartz mining interests are advancing. There is a good, healthy feeling in this branch of mining, which augurs well for its future. All over the State miners are at work, prospecting for and opening mines, and everywhere are the quartz mills pounding away on ore and turning out the gold bullion. The signs of the times are that California will soon show a gratifying increase in its gold product, and it even now keeps up in the yield with that of its younger competitors in the mining field, only one of which has been able to excel it in its annual bullion product.

Alaska Mines.

A paragraph is going the rounds of the press which sets forth in somewhat glowing colors the advantages of Alaska as a mining region. It speaks of various quartz mills on the coast, all paying, the placer mining on the Yukon river and the mildness of the climate. The article is somewhat misleading. The quartz mills are very few. The big one on Douglas Island is one of the most complete in the United States and one of the largest, and the mine pays well. But there are only one or two more in the Territory. Most of the quartz claims are undeveloped to any extent. The Douglas Island mine is a sort of quarry of low-grade quartz, and it took large amounts of capital to equip the mine with a snitable plant.

On the coast the weather is not so very severely cold in the winter, but in the interior the cold gets to be extreme. Thirty, forty or fifty degrees below zero is not uncommon in the depth of winter. The placer mining season is, of course, short. Several prospecting expeditions up the Yukon river revealed nothing that would pay to work under the existing circumstances. Lately it is stated that rich finds have been made somewhere along the river, and the miners from the other camps have gone in search of the new placers. Numbers of men have also gone from here to try their fortunes.

The country is not easily prospected. Dense forests, vast bogs and moss-covered tracts hinder travel. Communication in winter is by dog teams, and in summer by canoes. The country

is thinly settled and there are few towns or villages. People who go there must have well-filled purses and be prepared to undergo hardships and cold. Of course, at the coast settlements where there are towns, the miner would be all right, but once away from there he is in a wilderness where he must depend on his own resources. There are thousands of miles of unexplored region for the prospector to roam over if he cares to try his chances, but if he finds quartz mines in such places they are of little use. There are no roads at all. Placers, if they are very rich, would do quite well, or even if only three or four months' work could be done in a year they might pay to run. But men must bear in mind who go there that it is a hard country for a poor man, and it is no place for the "dead broke" to start for. Nothing very definite is yet known of the new placer fields, and the finds may have been greatly exaggerated.

Nominal Capital and Market Value.

A great many people have a mistaken idea as to the "capital" of mining companies. They see in the newspapers a notice of the incorporation of the "Great Horn Spoon Mining Company, with a capital stock of \$5,000,000 in 500,000 shares." They think that this must be a big company. But those who know how such things are done understand that there may have been only money enough actually subscribed to pay for filing the articles. Numbers of companies never had \$500 in the treasury at starting, and most of them want to sell a few shares for an actual working capital. Often the men whose names are used as incorporators have had shares given to them, and occasionally subscribe for more to start the company going. Again, the stock may be given a fictitious value of \$100 per share, and he sold for ten cents.

The census officials during their investigations received returns from 104 mining companies, whose aggregate capital stock was \$1,014,111,250, and the market valuation was only \$89,641,222. Some 43 of these companies, for instance, were Nevada incorporations with an aggregate capital stock of \$509,045,000 and a nominal market value of \$20,170,910. These show a representative example of the difference between nominal capital and market value.

The practice as to capitalization varies with the locality of the market rather than the value of the property. Even the quoted market value is largely fictitious, sales of a few shares often bringing much greater prices than could be obtained on any considerable portion of the entire property. A very large part of the best mines, too, are not on the market at all, and their owners, even if they desired to sell, could only tell the asking price, not that which could be realized.

We often see in the telegraphic news mention made of mining companies being organized with hundreds of thousands of capital. This always means capital stock, not capital, and it costs nothing to add a few ciphers to make the figures look imposing. It is very seldom we see a company organized with so small a capital stock as \$50,000, though of late years the practice is to reduce the figures materially from the old custom.

It is very hard to place an exact value on a piece of mining property. Mr. Alexander Del Mar has lately told them in London that the California custom is to value it at two years' product, or at the most three. That is, if the mine produces \$40,000 a year it is worth \$80,000. But that gentleman will find it hard to convince Californians that any such custom exists, or ever did exist; for a mine producing \$40,000 a year would sell for more than \$80,000 unless it was nearly worked out. There are so many circumstances to be considered that the price paid for one mine can scarcely form any basis for the value of another.

GOLD AND SILVER are reported as having been found in Boone and adjoining counties in West Virginia, by a "returned" California miner. The dispatch which announces this is as usual in such cases very vague, and again, as usual, there is immediate talk of a "syndicate" being formed to purchase a mine with a 22-foot shaft.

A DAILY train of 115 cars is now required to transport Comstock ore over the V. & T. Railroad to the stamp mill on the Carson river.

California Clays.

Clays of varying excellences are widely distributed in this State. Nevertheless, there are not more than a dozen potteries being operated, and all of these work mainly on the coarser sorts of crockery, such as stone jars, jugs and crocks, flower-pots and vases, ironstone, sewerage and drainage pipes, tiles, stove and flue linings, well tubing, water filters and coolers and receivers, and chemists and assayers' materials, fire-brick, terra cotta, etc. These establishments employ about 300 men, and the capital invested is about \$400,000. In the coast counties the potteries are operated all the year round without intermission. Those situated farther in the interior suspend operations during the winter, with the exception of the larger establishments, where work is done indoors. The long dry seasons of California greatly favor the business, enabling the potter to very effectually dry his wares and perform much of his work in the open air.

This industry has not grown very much, however, because there has been a limited market, owing to excessive foreign importations of such products. Table wares and better descriptions of pottery ware have not been made here as yet, those involving elegance of design and artistic skill having been neglected. Kaolin—porcelain clay—has been reported as found in a few localities, but no deposit of any size has been systematically worked or utilized in making porcelain.

State Mineralogist Hanks, while recently traveling on the stage line from San Diego to the Julien district, accidentally picked up a piece of rock, and on examining it found that it was a fine specimen of feldspar found in Norway. On continuing his investigations he also discovered pegmatite. These minerals are used in manufacturing the finest kinds of pottery and porcelain. Mr. Hanks states that the feldspar and the pegmatite evidently exist in large quantities in San Diego county, and as California also produces good clay, there is no reason why this State should not commence to manufacture the best and finest pottery and porcelain, which is now imported from Europe. Mr. Hanks has notified the principal potters in the State of his discovery. To begin the manufacture, however, would require considerable capital and the importation of skilled workmen. A prime requisite, however, is a good deposit of kaolin. This is known to exist in several places, but as to quantity no proper investigations have been made.

Foundry Notes.

The Union Iron Works were the successful bidders for the construction of the Spring Valley Water Company's Pumping Works at Black Point.

A Duncan concentrator is placed in position ready to be run at any time at the Pacific Iron Works, on First street.

The new engines and plant of the Electric Light Company, on Stevenson street, all made by the foundries in this city, are working very satisfactorily.

A Frishee-Lucop quartz pulverizer, such as described in the PRESS of last week, is running steadily at the Pacific Iron Works.

There are full supplies of pig iron on hand in this city and the consumption is light.

There is very little being done in the line of mining machinery at the city foundries. Several new mills are talked of, but orders are few.

The San Francisco Tool Company has plenty of work in its shop. The company is receiving abundant proof, in the shape of patronage, that its specialty of pumping machinery is appreciated.

A new style of dynamo is running the electric lights in the shop of E. H. Rix, on Fremont street.

Frank Huntington is manufacturing several of his quartz mills for orders. The mill is proving satisfactory, and is now in use in many places all over the coast.

At a meeting on Wednesday evening the boiler makers resolved to order a strike in the Union Iron Works, the movement to be altogether independent of the other iron trades.

The Pacific Rolling Mills have not only the contract for the iron and steel work of the new cable road in Oakland, but are building the whole road-bed, tube and all. The tube is quite large. A full gang of men is at work on the road.

Working Gold-bearing Sulphurets.

Concentration and Chlorination in Nevada County, Cal.—No. 3.

(Written for the PRESS by C. A. SCHENCK.)

Regulating the Concentrators.

Sometimes it happens that the belt travels too much to one side; but this is easily regulated by the last underneath-roller, counting from the head of the table, which goes by the name of the tightener. Screw the hangers slightly up on the opposite side, or loosen on the side to which it travels. It need scarcely be mentioned that to make this correction effective, all the other rollers, big ones as well as small, must be on line, and that the revolving belt and the ash-frames must be level in the direction of their shortest side. In a machine which is in good working order—well oiled and every part in adjustment—so-called sand-corners will be observed on the two long sides, extending from ore spreader to the foot of the table. This is the natural effect of the shaking motion, if the pulp on the table is not too sloppy. The water follows freely the continual change in the oscillating motion, while the sand from its nature is more retarded, and the consequence must be that the sand along the long sides is drier, is mixed with less water, than the balance of the pulp on the belt. The presence of these slight corners of sand is evidence, therefore, that the machine is in good working order, and that the pulp from the battery is not too diluted, in which latter case the corners and all the other stuff on the belt would be sloppy. It would be evidence, on the other side, that not enough water is fed in the battery if the two sand corners spread out too much toward the center line of the table.

It also happens sometimes that sand and water are distributed unevenly on a machine, different from the case just described, the sand working to one side of the table, making a heavy, broad corner, while the other is sloppy. This might be caused by some defect in the machine. Examine, therefore, all its parts; see if the pulp from ore-spreader and water from water-hore are uniformly distributed over the table; correct every jar which might be observed, and examine if the belt is perfectly level in the direction of its shortest side. If all this is found correct or put in order, and there is still no exact balance of the pulp on the belt, a heavy sand-corner forming on one side or the other—a small difference in the force of the swing to one side and then to the other can now be the only cause of the defect. If the momentum, or length of the swing to the right side, is greater than that to the left, a sand-corner is formed on the right, however small the differences may be. Move out, by a slight blow of the hammer, all the bottom bearings of the supports on the opposite side; these supports participate in the oscillating motion. The effect of this correction consists in increasing the force of the swing to this side and in lowering the table the same time; the equilibrium will now be obtained. The same effect can be produced by bending the circular spring in its short bent toward the side having the thickest sands.

Oiling is an important part in the management of Frue concentrators; the gudgeons of the small rollers receive only one or two drops of oil every other day at the Providence. Brasses and boxes of main shaft, boxes of big rollers, worm gear, etc., are oiled every day. Albany spindle oil is used to clean the boxes and gudgeons of the two lower rollers when they gum up and turn hard. Once in a long while the ash-frame is lifted out of its supports, especially if the head roller turns hard. The concentrates are scraped once a day out of the concentration box into a draining box and wheeled to the drying room after draining. Revolutions of crank shaft per minute, 190 to 195; travel of belt per minute, 34 to 36 inches; inclination of belt in 12 feet, three inches.

From the concentration room the sulphurets are wheeled into an adjoining room (provided with high windows) and spread out on the floor made of lumber. All lumps are broken by

means of a shovel in spreading out the ore. No artificial heat is used here to assist in the drying. From this room the sulphurets are wheeled into the furnace house.

Roasting.

The ore contains both silver and gold, and as the first-mentioned metal is also to be extracted in the subsequent process of lixiviation, the roasting has to be performed in such a way as also to suit this purpose.

It would be sufficient to give the ore a so-called "dead roast" if gold were only present; that is, to change the sulphides of iron and copper by gradually increased heat into oxides, converting at the same time the small quantities of the sulphide of lead (in the galena) into lead sulphate and lead oxide, of the zinc in the blende into zinc sulphate and volatilizing sulphur, antimony and arsenic in the form of volatile oxides, and also sulphites, oxides of lead and zinc escaping at the same time. The gold would then be in the roasted charge fit for the gold chlorination; any silver would now be present partially in the metallic state and partially as a sulphate and not fit either for amalgamation or leaching as the latter is practiced.

This latter circumstance, in considering the effect of a dead roast on the ore of the district in regard to the silver, necessitates therefore a

phate and also some chloride; zinc into oxide and chloride. All the sulphur is, or ought to be, expelled, with the exception of that in the sodium sulphates. All ferrous sulphates which was formed during the first period should be destroyed, as it would be most detrimental in the following extraction of gold.

Automatic Re-starting Injectors.

We give engravings on this page of Gresham's new patent automatic re-starting injectors for stationary, portable and marine boilers. These injectors took the first prize in the recent Inventors' Exhibition in England. Among their peculiar features the following may be mentioned: They are perfectly automatic and cannot fail to work as soon as steam and water have been turned on. They will work at any steam pressure ranging from 20 to 150 pounds, and may be placed above or below the water supply; if above, they will lift the water with certainty up to 17 feet. They have no handles; a common globe valve on the steam pipe to start the injector, and another on the water pipe to regulate the water supply, is all that is needed. By their re-starting quality they are enabled instantly to take up the feed-water automatically as soon as the supply, which may

SECTION ACROSS MOUNT MORGAN, WITH CUP-DEPOSIT OF GEYSER.

change in the roasting. This must be carried on in two periods of more or less length in reverberatory furnaces. The first period is an oxidizing one; the second a chloridizing, and during the latter the silver is converted into a chloride at a temperature, which again decomposes any monochloride of gold into its elements, so that the gold remains in the metallic state.

In the oxidizing period, part of the sulphur, arsenic and antimony escape in the form of sulphurous, arsenious and antimonious acids, metal oxides, sulphates, arsenates and antimonates being formed at the same time which are not volatile. If salt is now introduced these combinations are acted upon by the chlorine, hydrochloric acid and vapors of the chloride of sodium; chloride of silver is formed besides chlorides of the base metals, which latter mostly escape. The sulphur which still remained in the ore at the end of the oxidizing roasting, having formed sulphates

he temporarily interrupted, has been restored. It is claimed that they can take up with ease and certainty feed water of a much higher temperature than most injectors. These qualities render them invaluable as boiler-feeders, and particularly adapted to traction and farm engines, which have to run over uneven surfaces; also to tugboats and steamers, which are so liable to have their water supply interrupted by the motion of the waves.

The injector is attached in a horizontal position with the overflow pointing downward. Globe valves of suitable size are placed on both the water supply and steam pipes, and a check valve on the delivery pipe; all these valves should be placed as close to the injector as possible. A fine strainer should be attached to the water supply pipe to prevent the choking up of the injector with chips, weeds, etc. The steam is taken from the dome or top of boiler. The

EXTERIOR.

INTERIOR.

GRESHAM'S PATENT AUTOMATIC RE-STARTING INJECTOR

with the metallic oxides, enters into combination with the oxide of sodium, which is derived from the salt, forming with it sodium sulphate, which does not have any injurious effect in the chlorination and leaching of gold and the subsequent leaching of silver. That part of the sulphur which was yet combined in the form of sulphurets with some of the metals, as lead, silver, antimony arsen, etc., at the end of the oxidizing roasting is taken up by the chlorine, forming there with very volatile chloride of sulphur. The chloridizing period is therefore quite distinguished from the preceding by its absence of sulphurous acid, which was so prolific during the latter. No sparks are observed during the chloridizing period.

At the end of this roasting process the gold is in the metallic state; most of the silver is converted into a chloride, some sulphate and arsenate, and perhaps some metallic silver, may also still be in the ore. Copper and iron are mostly converted into oxides and various amounts of their chlorides; lead is changed into oxide, sul-

phates can be taken out for cleaning purposes by unscrewing the end pieces. Several sizes of these injectors are made by the Nathan Manufacturing Co. H. P. Gregory & Co., San Francisco, are sole agents for the Pacific Coast and Australia.

CABLE ROADS.—The statement sometimes made that cable railroads injure property near which they pass has been amply refuted by the experience in this city, where the contrary has been proven. In Los Angeles they not long since built a cable railroad on a route where there was no traffic, and with the sole purpose of bringing certain lands into the market, so as to sell the lands and also make business for the road.

The French Government has decided to lend 600,000,000 francs more to the Panama Canal Company.

ORANGE trees are being shipped to New Zealand, Florida and North Carolina from Pasadena.

A Curious Gold Mine—No. 2.

In last week's PRESS we gave some diagrams and a description of the Mount Morgan mine, in Queensland, where the gold is supposed to have been brought to the surface by means of a hot spring. One of the diagrams showed the method of building up of geyser deposits and subsequent denudation. Continuing the subject, we this week give a sectional view showing the structure of the mountain. In this cut *a* is the pipe of the geyser (theoretical); *b*, the cup-deposit of geyser; *c*, overflow-deposit of geyser; *s*, metamorphic rocks; *d*, rhyolite dykes. The sectional area of the cup-deposit is only approximately known. The depth of the cup-deposit is not known at all, further than that it must be less than the difference between the levels of the summit of the hill and the bottom of the Dee Valley. Lastly, the distribution of the gold throughout the whole of the cup-deposit is a pure assumption, in making which we are not assisted by a knowledge of any analogous case in nature. But the amount of auriferous rock in sight is enormous, and Prof. Jack states that there is no rashness in believing that it extends over a large area and to a considerable depth.

The mine has a 25-stamp mill, and many thousand ounces of gold have been produced. There is not a trace of silver in the gold obtained, which is said to be 99.7 fine—most wonderfully pure.

As we have stated, the discovery of this mine under these peculiar circumstances may lead to the finding of others in this country. A vast area of the Queensland western interior is covered with cretaceous rocks, and has been covered with sandstone, of which isolated tablelands remain to attest its former wide extension. Beneath the cretaceous rocks palaeozoic rocks undoubtedly extend, and these may contain many ledges or reefs as rich as those which are exposed to view in the ranges near the coast. With a hot spring rising from depths in which auriferous rocks lie, the phenomena of Mount Morgan may be repeated. Where there are "craters" or geyser deposits there might be chances of gold deposits, if these theories concerning Mount Morgan are correct.

Mining Accidents.

Wm. Eddy, superintendent of the Hickey mining property at Dutch Flat, was struck recently by a flying stone from a blast, which broke one of his ribs and smashed a watch which he carried in his vest pocket. His injury was quite severe, but no fatal result is anticipated.

At Lordsburg, N. M., on the 17th inst., Joe Randall and Alex. Rankin, miners, working in the Gibson mine at Victoria, near Gage Station, were instantly killed while drilling out an unexploded charge of giant powder. Both were so terribly torn to pieces that only parts of their bodies were found.

Wm. Phillips, for several years underground foreman at the Heslep mine, Quartz Mountain, Tuolumne county, has had his leg broken by the falling of a rock in the tunnel.

By a cave in the Quartz Mountain mine, Tuolumne county, on the 19th inst., Joseph Faull was fatally injured.

By an unfortunate mistake on the part of the engineer at the Tozer mine, Calaveras county, Clifford Miller, a miner, received injuries from which he died.

On the 23d inst. James McDade, a native of Scotland, aged 32, unmarried, fell down the Ohlston shaft, a distance of 135 feet. McDade was employed in repairing the pumps on the 2100-foot level, below the Sutro tunnel. The supposition is that in a moment of absent-mindedness he walked from the station into the shaft, killing him instantly.

Patrick Sullivan was killed in the St. Lawrence mine, Butte, by falling a distance of 500 feet in the shaft.

The renegade Apaches are making for the San Carlos reservation. Orders have been issued to kill them on sight, and \$2000 will be given for Geronimo or his head.

MECHANICAL PROGRESS.

Slow Power and Friction.

It has been shown that by properly applying a strong, slow moving power, a light-running vessel may be driven at a very high speed, and the question of how to accomplish this is principally a question of friction; for if the slow moving power be taken as a given number of "units of heat," obtained from the combustion of fuel, and transmitted by means of water and steam to the machinery or engines, then if the speed of the engines or piston travel be made too high, the wear and tear and friction use up a large proportion of such power, and the more mechanism there is in motion (that is, the greater the number of the working joints or journals) the more the trouble from the spring or elasticity of the material, the more the cramping and hindering of the posts, which will multiply the friction in a compound ratio of the number and speed of the moving pieces.

How then can this strong, slow moving power be converted into high speed with the least loss from friction? It has been seen that in the case of the wind as a power, a vessel sailing "close by," or within six points of the wind, may run ten miles an hour with a wind that itself only moves at the rate of eight miles. Here the question of friction is simplified down to, first the friction of the wind upon the canvas, and second, the friction of the keel upon the water. These two items of friction are great—far greater than most people would at first imagine; but they are far less than the waste of power in finest machinery man ever made. Wherefore, various and sundry attempts that have been from time to time made to make a vessel travel by means of a windmill driving a paddle or propeller, have all been ignominious failures in speed or economy of power.

Now, it is to be observed that the result spoken of in the case of a vessel sailing on a wind is attained by simply making the line of draught lie at such an angle in relation to the line of direction as shall compel the vessel to run fast to get out of the way of a slow coming wind.

Let the steam engineer also apply his power in a similar manner, and make his line of draught lie at such an angle to his line of direction as shall cause his vessel to run fast to give room for the movement of slow (and therefore possibly simple, durable and smooth-running) machinery.

In this matter the marine engineer compares with his railroad brother as the boy skating on smooth ice compares with the boy running on land, for the railroad man with the present style of locomotive must measure off mile by mile with his driving wheels, while the marine engineer may, with advantage, drive his boat ten miles, while his machinery would run only seven.

Overlooking and ignoring this principle costs many of our largest steamship companies a very large sum, both in coal bills and repairs.

No wonder our steamer-owners groan under their heavy burden while carrying near one-third of their expenses uselessly, either invested in spare boats or wasting in their furnace fires.

Fracture from Centrifugal Force.

The bursting of a wheel makes a very interesting problem to work out materially to agree with an accidental smash-up of an emery wheel. We hear of fly-wheels exploding. They broke all to pieces, smashed into atoms and flew in every direction, simply because the centrifugal force has an outward tendency in every portion of the wheel, and must break across in every diameter within the revolving mass. Take a chain of uniform strength, or a rope of equal size throughout its length, it would not be supposed that every link would give out at once, or that the rope would separate into its integral fibers, simply because every thread and every link is strained to its utmost and is on the point of breaking. The instant that a fracture occurs in any part of the chain, every link is relieved of its strain. The breaking force has no means of being sustained for the remaining portion of the chain to receive the same parting treatment. So with the bursting of a wheel; the breaking strain is in the form of a circle instead of a straight line, as in a chain, and stands ready to part in any point in its circumference. The emery wheel has every tendency to split into any number of radial divergences as in two or three equal parts, but the composition of a wheel of this kind, like everything else, has a place, a division line, that is not as strong as in the rest of the wheel, and when the limit of speed is reached a separation takes place at right angles with the circumference of the circle in just the same manner as with a tension rod that breaks square across with its central line. Only in case of the wheel the out-throw of the entire mass still exerts a breaking strain that increases gradually from the radial fracture till it is the greatest on the opposite side. This bending tendency must continue the fracture till the radial line becomes a diameter and the wheel is broken in halves. What takes place after this may have more to do with the bursting of the fly-wheel than when it exploded on the shaft. A three-line fracture would indicate a disturbance from internal strains due from unequal shrinkage.

STEAM GAUGES NOT INFALLIBLE.—Attention has been repeatedly directed, says the *Iron Age*, to the circumstance that steam gauges for boilers are not infallible, and that occasional comparison of their readings with those of standard and presumably accurate gauges is much to be recommended. Recent complaints among boiler-owners in Germany have given further prominence to the matter, and have pointed also to the important fact, generally overlooked, that the standard gauges themselves are not above suspicion. It was found that in many cases the test gauges used in the official boiler inspections did not furnish the same readings as perfectly new gauges of the kind to be used in every-day work, even when both sets of the apparatus came from the same maker, and the most natural inference to be drawn was that the repeated high pressure to which the so-called standard gauges had been subjected had seriously impaired their proper working. Mercury gauges, we are led to believe, are not generally at the disposal of the German boiler inspector, and boiler-owners must therefore be satisfied with the indications of the test gauges with which he is supplied. Testing the accuracy of these standard devices seems to be, incredible though it sounds, an unusual thing, and steam users appear to have every reason to be rightfully indignant at the existing state of the testing service. One of our German contemporaries points to the urgent necessity of reform in this matter, and its stand should meet with hearty support.

COMPOUND ENGINES.—One important function of the compound engine is the great augmentation of power that may be employed for emergencies, by passing high or initial steam into the compound or expanding cylinder. In this way the power is instantly increased to nearly the proportion between the two cylinders, or as to three to one, for example; and there are various cases when such augmentation, for brief intervals, would be desirable. The distributing valves would require no complication for this purpose, only a pass-over port and auxiliary slide of a simple kind. The compound engine will, because of its success and saving in marine and stationary service, be forced into uses where a loss instead of a gain will result. The higher degree of expansion gained is economy beyond doubt; but this economy is much less than is generally supposed, and easily neutralized by the addition of working parts required. In the case of locomotives, for example, the additional weight required is, in most cases, no objection; but the additional machinery becomes a very grave one, and in running expense soon equals the fuel saved by lower expansion. As a general proposition, separate expanding cylinders are not required or expedient, except in connection with a condenser. The power to which expansion is carried is, in a sense, a measure of the piston area acted upon by the condenser.

TO TEMPER TOOLS.—The quality of the steel should be uniform throughout; indeed, it is always better to have them tempered rather too hard than soft, for use will reduce the temper. If, at any time, it is necessary to perform the operation yourself, the best method is to melt a sufficient quantity of lead to immerse the cutting part of the tool in. Having previously brightened its surface, plunge it into the melted lead for a few minutes till it gets sufficiently hot to melt a candle, with which rub its surface; then plunge it in again, and keep it there till the steel assumes a straw color, but be careful not to let it turn blue. When that is the case, take it out, rub it again with the tallow, and let it cool. If it should be too soft, wipe the grease off, repeat the process without the tallow, and when it is sufficiently hot, plunge it into cold spring water, or water and vinegar mixed. By a proper attention to these directions and a little practice every workman will have it in his power to give a proper temper to the tools he may use. If a saw is too hard, it may be tempered by the same means, but as it would be not only expensive but in many cases impossible to do at home, a plumber's shop is mostly at hand, where the process may be repeated when they are melting a pot of lead. But here observe that the temper necessary is different to other cutting tools; you must wait till the steel just begins to turn blue, which is a temper that will give it more elasticity, and, at the same time, sufficient hardness.—*Industrial World*.

A NEW AND USEFUL ALLOY.—A new alloy that partakes of the nature and appearance of a brass, and also one that resembles nickel plate, has been recently brought out for which great claims are made. The exact proportions with which the metals are mixed, or even what are used, has not yet been divulged. Copper and tin, however, are the main ingredients. The alloy seems to have the properties of effectually resisting the action of the atmosphere, and will not tarnish under ordinary conditions. A dasher handle for a street car that had been hanging in a large stable, where it had been subjected to the action of ammoniacal vapors for three weeks, was barely dimmed in brightness, and it was quickly restored by rubbing with a dry piece of chamois. It is claimed that acids have no effect on it, except those that can touch gold. It is made of various grades and colors and is intended for use in the manufacture of car trimmings, valves, journal hearings, and all other places where the ordinary brass is now in use.

SCIENTIFIC PROGRESS.

DENSITY OF THE SUN.—Speaking of the density of the sun, Professor Lockyer says: If we take water as our unit of density, the density of the sun is 1.444. If we take the density of the earth as 1, then the value is about 0.25—practically a quarter. These values have been determined by taking the volume of the sun as given by the diameter of the photosphere—860,000 miles. Now, we have had to concede 100,000 miles for the height of one atmosphere above the photosphere, and 100,000 miles for another and it is not fair that those atmospheres should be left out of consideration; if we include these atmospheres, though we do not alter the mass, we alter the volume. If we put the same mass into a bigger volume, we naturally reduce the density. Now, if we take the atmosphere of the sun as extending to 100,000 miles above the atmosphere, that will give us a radius of 530,000 miles, instead of 430,000 miles, and we shall, as nearly as may be, double the sun's volume. Therefore we shall have halved the density. Instead of being a quarter as dense as the earth it will only be one-eighth as dense, and, instead of being just denser than water, it will be a little over half the density of water. The gases of the center may put on the appearance, if they do not put on all the physical properties, of liquids; but, be this as it may, in any region that we can get at, unfortunately limited to something like 400,000 miles away from the center, we are undoubtedly dealing with masses of gas.

HOW SAP FLOWS.—The sap of most plants is taken from the soil by the power of causing osmosis, sufficient to raise to what is generally known as "root pressure." In the stem the fluid passes through the vessels or ducts of the pitted cells or plants which, like the pine, have few vessels. These are all minute tubes, in which the sap is supported by capillary attraction, so that root pressure is generally considered to be amply sufficient to force the current to the top of the highest tree. But its motion upward is induced by the pumping action of the leaves, from which large quantities of water evaporate.

The ducts and pitted cells through which the stream flows are not entirely filled with sap, but include bubbles of gas with it. As water is withdrawn from the uppermost cells by evaporation the air in them expands to occupy the additional space, and so exerts less pressure than at first. This allows some of the water lower down to be forced upward and into them by the elasticity of the air bubbles in the other cells, the adjustment going on from above downward—the tendency being to equalize the gas pressure through the entire plant. While evaporation continues this equilibrium is never reached; when it stops the balance may be affected, and the sap remain quiet, supported by root pressure and capillarity, unless some disturbing element is introduced.

A STRAIN INDICATOR FOR USE AT SEA.—Mr. C. E. Stromeier recently described before the British Institution of Naval Architects an instrument that is likely to play a most important part in the future of marine architecture, and indeed in the designing of all large structures of metal subject to high stresses. Briefly described, the instrument consists of thin wire placed between two plates of metal, one being rigidly attached to the structure of the ship or other object to be tested, and the other held by a long wire and a coiled spring. The two plates are thus placed with their surfaces parallel, and only separated by the thin wire referred to, and which has attached to it a light pointer or needle. Upon any movement taking place in either of the plates the thin wire rolls between the two surfaces, and it will easily be seen that in this way the bending of a beam or the elongation of test-pieces when subject to stress can be defined and registered. The idea has not yet been fully worked out, and doubtless improvements in detail will be made; but the apparatus is in a fairly practical form and capable of doing useful work. It cannot fail to have a great future before it, and bids fair to occupy much the same position in relation to naval architecture that the steam-engine indicator does to the steam-engine.

THE HEALTH-GIVING PROPERTIES OF RAIN are not appreciated by the general public. Rain is an essential to physical vigor in localities that have any extensive population. Man and his occupations laden the air with countless and unclassified impurities. The generous, kindly rain absorbs them, even as a washerwoman extracts the dirt from soiled clothes. The ammoniacal exhalations, the gases resultant from combustion and decay, are all quietly absorbed by a hriek shower. People talk about a "dry climate," but it is a snare and a delusion. There is nothing in it. A very dry climate will never support a large population, for it would soon become so poisoned that it would be fatal to the human race. A scattering few might inhabit it, but not the multitude.

A NEWLY-DISCOVERED AND NEWLY-FILLED LAKE.—The discovery of a hitherto unknown lake in the Persian desert was announced at a late meeting of the Vienna Geographical Society. It is at least 25 miles long, and from Mohammedan evidence appears to have dried up after a previous existence, and to have filled up at a quite recent date.

NOTES ON CAST IRON.—Cast iron is stronger in compression than wrought iron, but much weaker in tension. It is not so safe as wrought iron when subjected to impact or suddenly applied loads. If the thickness of different parts varies much, the casting will be strained in cooling. All edges should be well rounded and the hollows filed. Iron expands at the moment of solidification in casting, but contracts in cooling. The contraction varies with the size and thickness of the casting and quality of metal. One-eighth inch per one foot is generally allowed in small patterns for shrinkage. Chilled cast iron is ordinarily cast iron rapidly cooled during solidification, by using a solid cast iron mold protected by a wash of loam, causing a chemical combination of the molten iron and carbon. Very hard. Fracture, silvery. Direction of crystallization strongly marked. Malleable cast iron is made by heating ordinary casting from two to forty hours, according to size, in contact with oxide of iron or powdered red hematite, causing partial conversion into wrought iron by abstraction of carbon. Toughened cast iron is produced by adding to the cast iron, and melting among it, from one-fourth to one-seventh of its weight of wrought iron scrap, which removes some of the carbon from the cast iron and causes an approximation to steel. The melting point of cast iron is 2750° F.; that of wrought iron or steel is 3250° F.

THE MOVEMENT OF GLACIERS.—The cause of the movement of glaciers is still to some extent a disputed question. It was formerly claimed by some that ice was of a viscous nature like tar, and flows under the influence of gravitation, like any similar substance; but experiments have shown that, while ice can be bent in any direction, it cannot be drawn out, but always breaks when pulled apart. So, when a glacier falls over a cliff, it does not flow smoothly over, but is broken up into separate fragments, which reunite again on reaching a more level part of the valley. It is probable that the motion of a glacier is due to the principle of regelation, and that the attraction of gravitation and the pressure of the snow and ice in the upper part of the glacier force it along, while the ice is being continually broken apart and pressed together again, thus adapting itself to all the windings and inequalities of the valley in which it flows.

A NEW THERMO-CHEMICAL BATTERY.—Professor Riatti, the Italian chemist, has brought forward a new kind of thermo-chemical battery, in which the production of the current results from the difference of temperature of two layers or strata lying at different levels in a vessel filled with liquid. This cell consists of a wooden box or vessel, traversed by two copper pipes, placed the one over the other, and separated by a distance about equal to half the height of the vessel, the latter being filled with a solution of the sulphate of copper. A current of steam passes through the upper tube, and a current of cold water in the lower, with the effect that copper is deposited on the latter, while the substance of the former is reduced. By changing from time to time the position of the tubes, equilibrium is established. The battery is said to work well and not to polarize.

INFLUENCE OF THE MOON ON A MAGNETIZED NEEDLE.—M. G. Ligner has made a remarkable communication to the Meteorological Society of Austria. He has ascertained, after a number of careful experiments, that the moon has an influence on a magnetized needle varying with its phases and its declination. The phenomenon is said to be more prominently noticeable when our satellite is near the earth, and to be very marked when she is passing from the full to her first or second quarter. The disturbances are at their maximum when the moon is in the plane of the equator, and greater during the southern than the northern declination.

ORIGIN OF SULPHUR IN COAL.—M. Dieulefait has been inquiring why there is so much sulphur in stone coal, and why there is so little of free alkaline carbonates in the ashes. For this purpose he has analyzed the surviving species of the families of the coal plants, particularly the equisetaceae, and has found in them a proportion larger than usual of sulphuric acid. Hence he deduces, as the answer to his questions, that the coal plants were more highly charged with sulphur than most existing plants, and that for that reason their alkaline constituents assumed the forms of sulphates instead of carbonates.

THE REPRODUCTION OF ELECTRICITY.—M. Marcel Deprez has brought to the notice of the Academie des Sciences an ingenious instrument for reproducing at will an invariable quantity of electricity. It is a voltmeter hermetically sealed, and thus rendered independent of barometric or hygrometric fluctuations. The water decomposed by the current during each operation can be reconstituted afterward by passing a spark between two wires sealed in the upper part of the tube.

ORIGIN OF NITROGEN IN SOILS.—Prof. W. Mattieu Williams indicates as probable source of nitrogen in soils, and serving as food for plants, the bodies of insects, excreta of living insects, invisible spores, microbe and particles of organic fluff which are always floating in the air and liable to adhere to the moistened surfaces of the soil and of the leaves of the growing plants.

ENGINEERING NOTES.

The Panama Canal.

This immense undertaking seems to have reached a crisis. Dr. Wolford Nelson, formerly a member of the Board of Health at Panama, recently arrived at New York from the isthmus, and in an interview has said: "If De Lesseps is correctly reported by the press as saying that half the work on the canal is completed, the statement is willfully misleading to the French people. A fearful crisis has arisen in canal affairs. The company's indebtedness to the share and bondholders now amounts to about \$160,000,000, on which they are paying an annual interest of \$6,000,000. It is reported on excellent authority that the company has exhausted its funds and is working on borrowed capital pending the floating of a new loan of \$120,000,000. For months past this work has been dragging, and quite recently, Boyer, the chief director, called some of the contractors together and requested them not to push the work. This was done, presumably, to cut down the expenditures."

And now comes a still more damaging report from the French engineer, sent over by the government for the special purpose of reporting upon the condition of the work. M. Rousseau, the engineer referred to, reports that the canal company's statement respecting its facilities for construction is incorrect. He thinks it will take more time and cost more money to complete this canal than the canal company have represented. It is now said that the French Minister of Public Works will inform M. de Lesseps that he must reply to M. Rousseau's report, which means, of course, that he must show that the canal company's estimate was correct. The weight of evidence all along has been that the canal company has represented the work on the canal as more extensive than the facts would warrant. M. Rousseau now gives official indorsement of those representations. The canal company will not be allowed to issue the proposed lottery bonds until they have convinced the Minister that their former report is in the main correct.

In the future there is the chance of the Nicaragua canal and the Eads ship railway—the latter having been recommended by the President as worthy of national aid. M. de Lesseps is a man of fertile resources, but the present indications are that he has a work on his hands that will test his best powers.

THE TELEGRAPH IN CHINA.—The most recent link in the long chain of telegraph lines which is spreading with such rapidity over China is the land line from Shanghai to Canton. A line from Peking to Tientsin was opened a few months ago, and the capital of China was connected directly with London. Now the capital of Southern China is joined with the metropolis of the north; and as Canton was put in communication by telegraph with the frontier of Tonquin at the outbreak of the present political troubles in the latter district, the telegraph now stretches in an unbroken line from Peking, in the north, to the most southern boundary of the Chinese Empire, and a message either from London or Peking might reach the headquarters of the Chinese forces on the Tonquin frontier in a few hours. Four years ago the only telegraph line in China was one about six miles in length, stretching from Shanghai to the sea, and erected to inform the mercantile community of the arrival of vessels off the mouth of the river. The next important line constructed by the Chinese Government will probably be one uniting Peking with the great northern line across Siberia at Kiachta. This will have to cross the whole of Mongolia, and will give the capital of China a third alternative telegraph route to Europe, a matter to which some political importance is attached in China. This extraordinary development is due solely to political considerations.

ENGINEERING AT CAMBRIDGE UNIVERSITY.—Old Harvard is fast coming into line as a university where a practical education can be obtained. To some of the old school such changes may appear destructive of ancient traditions. Among other things, the establishment of engineering, as a recognized avenue to a degree in honors is decided on, which will considerably augment the points of contact of the university with the life of the people at large, and will be but a step toward still further realizations of the broadest possible ideal of a university.

CONNECTING THE HUDSON WITH LAKE CHAMPLAIN.—The construction of a ship canal to connect the Hudson river with the St. Lawrence river by way of Lake Champlain, is regarded as a feasible enterprise. A canal 131 miles long would enable vessels of 1000 tons or even larger to go to New York from Chicago two days quicker than boats now go from Buffalo to Albany on the Erie canal, whereas now grain shipments are being diverted to Baltimore and Montreal and other points more and more every year.

A LARGE PULLEY.—In England a pulley 63 feet in diameter, and weighing 83 tons, has just been made. It has grooves for 32 ropes, which together will transmit 1280-horse power, and the rim will have a velocity of more than a mile a minute.

USEFUL INFORMATION.

FIRE-PROOF BUILDINGS.—Few things in connection with buildings, remarks the *Fireman's Journal*, are more generally misunderstood than fire-proofing. The old error that buildings made of incombustible material will be fire-proof has at last been exploded by the destruction of great numbers of structures built in this way. Now vast sums are spent every year in making iron buildings fire-proof, because people have the vain notion that to be fire-proof means to be incombustible. This is a very costly mistake, and it is to be hoped that at some future time it will be understood that buildings may be constructed of brick and wood which shall be as perfectly protected from fire as the huge iron buildings that are now going up. A wooden beam protected from the air will stand a much higher and longer continued heat than iron. The coating of charcoal that has formed on the surface of the wood prevents the penetration of the heat into the interior. If the access of air is prevented, the strength of the wood is not impaired by hours of exposure to a high heat. Demonstrations of this may be seen at almost every large fire. Floors and partitions of wood, if properly defended by the use of plaster, with beams inclosed in a manner similar to that employed for iron, will give, at a comparatively small cost, a very good fire-proof structure. There is, indeed, no reason why all buildings should not be made so nearly fire-proof that any one floor could be burned out without causing damage on the other floors of the same building. This value of a building that will not burn under any ordinary conditions, and which will not take fire readily from a general conflagration, is so great that architects will probably not long neglect this branch of construction. We may expect, before long to find that there are cheap as well as costly ways of fire-proof construction.

REGISTERING THE SPEED OF RAILWAY TRAINS.—The apparatus for registering the speed of trains, in use on the German railroads, has recently been improved. The position of the train at any point on the track is registered by means of an apparatus consisting of two upright vessels containing quicksilver, and communicating with each other, one of which is exposed to pressure on the rail which causes the mercury to fall in it and rise in the other vessel until it reaches a wire and closes a circuit which causes a small knife in the station to cut a square-cornered hole in the strip of paper, which travels at a uniform speed, so that the time when any point on it passed the knife is known. Large numbers of this useful device are now being used on Eastern trains.

ALL is not gold that glitters applies to foils as well as metals in their original metallic state. The painter may purchase gold leaf, which is not gold, but a mere composition, or it may be yellow Dutch metal. For gold leaf he must pay seven or eight dollars for a pack of say 500 leaves. For the other two kinds of so-called gold foil he need pay only \$2 or \$2.50. The composition gold leaf has 500 leaves, while the Dutch metal has 1800 leaves in a pack. Then there is the silver leaf, white Dutch metal and nickel leaf. Dutch metal being cheaper, is often used in place of silver leaf.

TELEPHONE WIRES SOON WEAR OUT.—"The life of a telephone wire," said a telephone line-man, "is, as a rule, a very short one. It is much lighter than a telegraph wire, and is constantly liable to be broken. Sudden contractions of frost will frequently break it. It may be worn in two by chafing against brick walls; it may be cut by firemen, or it may be severed by many other agencies. The result is that in four or five years the wire is likely to be worn out. Telegraph wires, which are thicker, usually last much longer."—*Chicago News*.

FIRE-CRACKERS ARE MADE by Chinese convicts, hired by manufacturers from the Government at three cents a day, the work being done inside of the prisons. The paper is made of bamboo fiber. Each cracker is filled, rolled, and pasted by hand, with astonishing rapidity. The powder used is equal in strength to our best blasting powder. In 1884 about 500,000 boxes of crackers were imported to this country. Each box contains 40 packages, and each package from 64 to 80 crackers.

A NEW kind of concrete is now being used for building purposes in Paris. It is composed of eight parts of sand, gravel and pebbles, one part powdered cinders and one and a half parts unslacked hydraulic lime. These materials are thoroughly beaten together, the mixture forming a concrete which sets almost immediately, and becomes in a few days extremely hard and solid. It is said these qualities may be improved by the addition of one part cement.

RED WATCH HANDS.—To make watch hands red this recipe has been recommended: Mix to a paste over a lamp one ounce of carmine, one ounce of chloride of silver and a half ounce of tinner's japan; put some of the paste on the hands and lay them face upward on a sheet of copper, which must be held over a lamp until the desired color is produced.

RATS EATING PUTTY AND PAINT.—Prof. F. H. Storer reports in the Bulletin of the Bussey Institution the results of a series of experiments in the above-named direction. Mice, so it seems, not only do eat putty, but also red lead mixed with putty, without injury. They thrive on the linseed oil used in the manufacture of this most unsavory side dish, and the whitening which forms the other ingredients of "putty" seems to neutralize the evil effects of the lead. The bearing of these facts is important from a sanitary point of view, as Prof. Storer shows that the effects of mice eating away the packing of valves of drains and closets is an immediate frustration of the best efforts of plumbers and sanitary engineers to keep human habitations free from sewer gas. Not content with mice, the professor tried similar experiments upon rats, when it was found that "rats, when kept upon a rather short allowance of oats, ate putty freely." Finally, "the surviving rat was fed with 'plain putty' for a day or two, after which he received and ate (poor wretch) each day, for two days, a ball of putty made with a mixture of equal parts of slacked lime and whitening. He was next given a ball of putty made with a mixture of one part of oxide of zinc and three parts of whitening, together with 2½ grams of oats, and although he ate very little of the ball, he died soon afterward." The chief results of these experiments appear to be the injury rats and mice may do to houses, and the curious protecting effect of whitening as an antidote to such active poisons as red and white lead and carbonates of baryta.

CAR HORSES are the best fed and most carefully looked after of all work horses, yet their average years of service are less than four, on the road; but if taken off in season they will still do good service for some years on farms, where they can work on soft ground.

BIRD OIL.—A large amount of oil exists in the stormy petrel, and when fat, according to Brunnich, the inhabitants of the Faroe islands use it as a lamp, obtaining their light from a wick drawn through the bird's body.

AN AMUSING EXPERIMENT.—Select several cards of different colors, and in the center of each fasten by a little maulage a small, round piece of black paper. Place over the card thus prepared a piece of thin white tissue paper. The variety of hues which the black assumes is very amusing.

TO SOFTEN WROUGHT IRON.—Treat the iron to a low red heat and cool it in soft soap, and then reheat to a low red and let it cool in lime. It makes wrought iron very soft.

GOOD HEALTH.

Our Sleeping-Rooms.

It is to be regretted that paperings or carpetings should ever be used in the sleeping-room. Alas! what evil is lurking in the area of the four square walls which encompass us! What enemy is that, although trodden upon, yet is not subdued! Let the walls of our sleeping-rooms be kalsomined and the carpets removed from the floors. Let the crevices be carefully filled with putty (any one can do this), and the floor neatly painted or stained. A rug at the bedside, with small ones at the bureau and commode (Kensington rugs), will relieve the nakedness of the floor. These should be carried out weekly, thoroughly shaken, and exposed for an hour to sun and wind. Towels and wash cloths used during the day should never remain in the room during the night. I have seen wash cloths, used day after day in a sleeping-room, become sour and musty, emitting a strong odor both disagreeable and unhealthy.

The water-can and the entire toilet set must be kept perfectly sweet and pure. I do not mean merely clean to the eye, but clean enough for a chemist's use. Attention must also be called to the tooth-brush, which should always be thoroughly cleansed after using, and placed handle down, in an upright holder. I have found odor enough about one tooth-brush to infect the atmosphere of a common sleeping-room. In regard to ventilation, open as many doors and windows as permissible, avoiding a draft; but moving air is absolutely indispensable to the health of the sleeper. Let the bed stand as near the center of the room as possible, but on no account close to the wall. No one house-keeper may be able to carry out all of these suggestions, but it is the ideal, or housekeeping as it ought to be, which should be held up to the eye of the reader, that each one may choose what she can best carry out in her daily practice.

HOW TO BRUSH THE TEETH.—This is a matter of no small importance. Most people brush across the teeth from right to left. This matter of brushing will not remove the accumulations from between them, but tends rather to force the debris into the interstices. The brush should be placed against the teeth at the gums, and rotated toward the masticating surfaces of the double teeth. The mouth should then be thoroughly rinsed with tepid water.

SALICYLIC ACID SUET is used in the German army as a remedy for foot sores, etc., instead of the salicylic powder formerly employed. It is composed of two parts of pure salicylic acid and 98 parts of the best mutton suet.

The Mind and the Legs.

Men generally cross their legs when there is the least pressure on their minds. You never find a man engaged in business with his legs crossed. The limbs at those times are straighter than at any other, because the mind and body work together. A man engaged in auditing accounts will never cross his legs; neither will a man who is writing an article, or who is employed in any manner where his brain is actively engaged; when at work in a sitting posture the limbs naturally extend to the floor in a perfectly straight line. A man may cross his legs if he is sitting in an office chair discussing some business proposition with another man, but the instant he becomes really in earnest and perceives something to be gained, his limbs uncross quick as a flash, he bends forward toward his neighbor and begins to use his hands. That is a phase that I believe you will always observe. Men often cross their legs at public meetings because they go there to listen, or to be entertained; they are not the factors in the performance, and they naturally place themselves in the most comfortable position known to them, namely, that of leaning well back in their chairs and crossing their legs. A man always crosses his legs when he reads a newspaper, but is more apt to lie down when he reads a book. He reads the paper, of course, to inform himself, but at the same time the perusal of its contents is recreation for him, and his body again seeks its position of relaxation.

When a man is reading a newspaper and waiting for his breakfast his legs are always crossed, but so soon as the breakfast is brought to him he puts the paper aside, straightens out his legs and goes to work; that is, begins to eat, his mind now turning on the duties of the day before him. Men cross their legs in a ball-room, but it is far from an elegant thing to do, and is not done by those who have been brought up in good society. It is your "three-penny-bit" young man who crosses his legs at a ball, and, would you believe it, I have seen young ladies do the same thing.—*Denver Republican*.

CARE OF THE HANDS.—If the hands are stained, use a handful of clean sand in the water, rubbing it on the stains. This sand can be rinsed off and kept in a dish for daily use. Oxalic acid will take off stains, but it is rank poison and dangerous to have about; it also makes the hands exceedingly harsh. They must be washed thoroughly in tepid water to insure its entire removal, then rubbed with glycerine. The use of too much glycerine makes the hands moist and cold or clammy, and very disagreeable to the touch. Never hold the hands near the fire while rubbing with glycerine, as it dries in places before penetrating, leaving the hands harsh. Many house-keepers have rough hands in winter, which grows very painful, cracking open on the knuckles, the cracks extending into the palms of the hands. They take their hands out of hot soapsuds or starch to hang clothes out in the wind. If they did not use hot water, and the hands were thoroughly dried before going out, this would be avoided. A pair of white woolen stockings, cut off rounding at the ankle and sewed across, with a thumb sewed in, make a very comfortable pair of mittens for hanging up and taking off clothes. Pin them fast to the sleeves with large safety pins before going out, having first stretched the arm upward; then they will not come loose and the wrists will be protected. After bringing in the clothes, if the mittens are put in the clothespin bag they will be kept clean and in the right place. Hands are injured in very cold weather by lack of protection at the wrists, as large veins and arteries are exposed. The blood is chilled in passing into the hands. Every one cannot have handsome, white and shapely hands, but every one can have clean and comfortable hands.

NO WARMTH IN CLOTHES.—It is a mistake, says the *Lancet*, to suppose there is any warmth in clothes. Animal heat is the direct result of change, going on within the body itself. Nutrition by food, and the discharge of energy by exercise, are the sufficient causes of heat. Clothes seem to warm because they prevent the cold air, and objects with a capacity for heat, which surround the body, from attracting the heat generated within its organism. The clothing is simply an insulator. It follows that it should be light in weight, and above all things, it should permit the free and full circulation of blood through every part of the system—to the end of the finger and toe—and that the muscular apparatus of the extremities should be in perfect working order. If we will wear foot-coverings, whether boots or stockings, which compress the feet and render the separate action of each toe impossible, it is simply absurd to expect to be warm-footed. Heat is the complement of work and nutrition; and if a part of the organism is so bound that it cannot work, and its supply of blood is limited, it must be cold. The resort to stouter and heavier clothing under such circumstances is simply ridiculous. Generally it is the stockings that compress the feet. The garter acts as a ligature, and diminishes the blood supply, while the stocking itself acts as a bandage, and impedes the circulation through the extremities.

BISULPHIDE OF CARBON. M. Pasteur thinks, will become the most efficacious of all antiseptics, as it is also the cheapest, costing but a fraction of a penny per pound in large quantity.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

Downs.—Amador Ledger, May 22: Extraordinary progress has been made in draining the shaft. Work was started last Monday week, and by next Monday they expect to have the water all out. Water is raised at the rate of 240 gallons a minute by means of an iron tank. Sinking will be commenced as soon as the pump, now being made at Donnelly & Howard's foundry, is put in. It is the intention to sink the shaft 200 feet deeper before any drifting is undertaken. There seems to be an impression that the ore-body pinched out, and that this was the reason why work was suspended three or four years ago. This is a mistake. There was a fine body of pay ore in the bottom of the shaft, and all the signs favored the impression that the quartz extended to greater depths. The shaft is now 500 feet on the incline; the proposed sinking will carry it down to 700 feet.

South Spring Hill.—This company called for bids last week for sinking the shaft 100 feet deeper. Several bids were sent in, and the contract was to have been awarded last Saturday, but it is probable that all bids will be rejected, and the work done at regular wages. It has also been decided to add ten more stamps to the mill forthwith. This work will be commenced inside of a week. The sinking of the shaft will take about two months to complete. It will give a total depth of 820 feet. The additional ten stamps are expected to be ready by the time that the sinking is finished. The tunnel which is being run from the side hill to connect with the shaft is almost completed. It will be of material service in the drainage of the mine.

Miscellaneous.—The New London, near Plymouth, is looming up splendidly. The rock that has been taken out is exceedingly rich, and all indications point to a permanent paying mine. The owners have purchased the adjoining claim, the Pioneer, from John Evans and others for \$7500, also a tract of land from J. Woolford for \$4000. The Arroyo Seco gravel claim, near Irish Hill, in Lone valley, has been damaged to the extent of \$10,000 by the floods of the past season. The last heavy rains inflicted the greatest damage, covering up the machinery with debris. It is understood to be the intention of the owners to place the claim in running order again. At the Zeile, the repairing of the shaft is still the work on hand. All the difficulties of the cave have been overcome, and they are engaged now in retimbering where necessary. It will perhaps take a month or so to complete the repairs. At the Kennedy they have commenced sinking. The first set of timbers was put in the middle of last week. Mr. Thomas, the underground manager, has strong hopes of developing a mine on this old claim. The gravel claim of J. T. Wheeler continues to turn out remarkably well. Chunks of gold varying from \$100 to \$200 are frequently met with. One piece obtained within the past month is said to be worth about \$140. At the St. Julian a pocket of rich ore was struck last week. The extent of the pocket we have not learned. At the Moore they are about through with sinking for the present, and drifting toward the ledge is in order. This will take a week or more to complete. The mill will be started soon, and probably kept running for some time. The Tellurium, at Pine Grove, is still working. It is the general belief that the ore will pay well if a practical method of saving the gold can be devised. The ordinary mill process appears not to answer for this character of ore. The ore assays handsomely, but the yield by mill process is next to nothing. The Quartz Mountain mill has come to a standstill, to enable some changes to be made in the machinery.

Calaveras.

Riverside Mine.—Calaveras Chronicle, May 22: We have heard it rumored that the Riverside mine, in Hundred-Ounce Gulch, owned by Messrs. Nuner & Lowrey, is about to be sold. As far as the work of prospecting the vein has been carried on, the showing is remarkably good, judging from the specimens of rock we have seen, and warrants great expectations.

El Dorado.

Notes.—Georgetown Gazette, May 22: The Lone Jack mine near Garden Valley on Greenwood road will be started up to-day. A mill is to be erected at once. The Esperanza mine is still sinking. It is said Burlington is to have charge of both mines, the Lone Jack being a short distance to the north. D. C. Lewis, one of the owners of the Lone Jack, will return in a few days. Taylor mine will be in operation soon. Mr. Burlington has returned from San Francisco, and removed his family to the Esperanza mine. The new mill being put up on the Robert Burnham mine, north of Georgetown, will be ready to start up in a few days. The Slate Mountain mine continues to keep its mill busy on high grade ore. Work of development on the Alpine mine is progressing favorably. We learn they are taking out some high grade ore. We are also pleased to hear that Dr. Spencer is drifting on a fine body of pay ore from the shaft on his O. K. mine to the east of Georgetown.

Lotus Notes.—Cor. Placerville Observer, May 22: W. E. Everson and Ralph Heikens, of Coloma, are still driving at the Last Chance mine. They are in some 250 feet with the tunnel, and are now raising and stoping. The ore improves with development, and, on the whole, the outlook is most gratifying. Lewis Stricker, of Coloma, is now working on the Hardscrabble mine, southwest of this place, he having accepted the place made vacant by the resignation of Chas. Schultz. Henry Baumbach still holds his old position.

Grizzly Flat.—Our merchants are looking decidedly pleasant, now that the placer miners are beginning to bring in gold dust, the result of their winter run. J. M. Oxley's claim, near Middle creek, paid \$8.25 per ton to the man, including all work in opening the claim and cleaning up. He is now making another run. The adjoining claim, belonging to W. T. Henson, is looking fully as promising. Kendall and Russell are now cleaning up, and judging from their smiling countenances, they

are pleased at what they see. Philip Oswald is cleaning up, and is elated over the prospects so far. Marshall and Hun are running regularly, and are satisfied with appearances. Tholen and Norman are pushing their work, showing a fine body of gravel. It is reported that the Stillwagon mine is about to be bonded to capitalists. This mine contains high-grade sulphide ore, and with proper appliances for disulphurizing would make a fine-paying property. The Mount Pleasant is making new and rich developments. E. Williamson has a large body of rich gravel, and is succeeding well with his gravel elevator.

Nevada.

Ridge Mining Notes.—Grass Valley Union, May 20: Since the stoppage of hydraulic mining by the Sawyer decree, quartz prospecting has taken the leading place in mining, and some promising developments have been made. At Graniteville a good deal of such work is in progress, and this coming summer a good force of prospectors will be at work. The same can be said of Moore's Flat. McKillican has opened a fine ledge in that part of the county of very rich ore, and is taking out a large amount of gold. At Bloomfield the Derbec drift gravel mine is running full handed, employing over a hundred hands, directly in the mine, and hoisting 300 carloads of gravel daily for washing. De Noon, who has a lease of the old Derbec tunnel, is doing preparatory work and will soon have a full crew breasting out gravel. The Last Chance Company have at last reached the bed-rock, and expect to strike gravel within the next few feet. The Delhi mine, at Grizzly Ridge, is running 30 tons of ore daily through their eight-stamp mill. The ledge is tapped by a tunnel, and there being no hoisting or pumping to be done, the ore is mined and milled at a small cost. Ore of the value of \$250 a ton can be worked at a profit. The ledge ranges in width from 3 to 16 feet and being of a soft nature is very friable and easily reduced. A tunnel is being run to tap the ledge at a low depth, and where good backs can be obtained. Near Columbia Hill there are many quartz ledges which need only exploitation and some capital to commence operations to develop large mines. The Milton Company is prospecting for drift gravel near Cherokee, and from present indications will soon have enough ground opened to require a large force of men. As hydraulic mining seems to decline, more attention is being paid to the hitherto neglected quartz veins, and the salvation of the upper country, where hydraulic mines have been the mainstay, may yet depend upon quartz.

The Mother of the Gravel Mines.—San Juan Times, May 20: The prospectors on the ledge at Armstrong's ranch are down over thirty feet. They have struck rock full of sulphurets, and many pieces of rock that show free gold. The owners of the ledge are greatly elated, and believe they have a bonanza. One of the proprietors, more enthusiastic than the others, swears that they have found the mother of the rich hydraulics mines in this vicinity.

Quartz on the Ridge.—Grass Valley Union, May 22: The quartz discovery on the ridge continues to excite great interest in the vicinity of Sweetland, and the large vein upon which excellent prospects have been found at several different points has caused the tracing of the ledge to the South Yuba, which river it crosses near Jones' Bar, at a point about three-fourths of a mile below the crossing of the Grass Valley and San Juan Turnpike. The ledge shows boldly on the south bank of the river, where other locations have been made, and where the ledge can be opened upon by means of a tunnel. That the ledge crops to the surface in the country south of this point has not yet been demonstrated, but as far as traced from the middle to the south Yuba it is a very strong and well-defined ledge, and if the prospects continue to be as favorable as already obtained very important results may follow to the quartz mining interests of the county.

Placer.

California.—Placer Herald, May 22: Adjoining the Cressus mine in Baltimore ravine, to the west, is the California quartz mine, a valuable property. The rock in the tunnel is very hard, however, in places, costing \$200 a foot to run. Lately it is getting softer. A mistake in measurement was made of 50 feet, and there is about 42 feet yet to run before striking the ledge, when we may expect some good results. The superintendent has had a tedious time, but his faith and perseverance are equal to the task.

Plumas.

Prattville.—Cor. Plumas National, May 21: C. W. Reed, of Sacramento, came up to look after the interests of the Dutch Hill mining property. The company will work the property this year themselves. James Brewer has been selected as superintendent. They will have honest, faithful, competent service. White and McMillan still gather in the "golden sands." They work but a few men, but get good pay. Ellis, Bressler and Firmstone are taking out a large amount of gold on Clear creek. They are making many improvements, and are getting good pay for every day's work. They have eight or ten men at work, but will soon increase their force. C. C. Brown is one of our most prosperous miners, and he says his mine never looked so well as it does this spring. Somehow, every one expects to hear of a great find being made at Sunnyside, though little work is being done there at present. All along the North Fork the feeling prevails that we shall have such a year of prosperity as shall make glad the hearts of ye old-timer, and make the new arrival feel rejoiced that he came.

Spanish Ranch.—Many mines are situated within an accessible radius not a few of which are valuable. The most note-worthy are the Gopher and Badger Hill Hydraulic mines, the Brandy Flat, the Edman, and Hallsted mines, and smaller ones which space does not permit me to mention. All are in full operation, and judging by the amount of dust which is daily brought here and sold, they must pay richly.

San Bernardino.

The Oro Grande Boom.—Cor. Calico Print: The boom has at last reached Oro Grande. Whether we are impelled by sympathy reflected from the San Bernardino boom, or that the mantle of Colton has fallen upon us, I cannot say, but I can say that the boom is here, and that the thun-

der is real, not artificial. Much quiet development is going on in the mines. However, I am not an expert and do not pronounce authoritatively upon the subject. Still, men in whose skilled judgment I have confidence, and in whose integrity full faith, assure me that there have been recent developments in both the eastern and western camps of fine promise for the mining future of Oro Grande. The plain truth, however, is that we are practically without capital to do anything beyond amateur work in our mines. Poor men cannot make much headway in opening even valuable low grade mines in this section; but a good beginning has been made. Mr. Dana has a great pile of assorted ore here from his promising mine in West camp. I have specimens which are quite rich in horn silver. In East camp there are several men at work, on a mine owned, in part, I think, by Mr. J. M. Miller, of Calico, and Mr. Sparkuhle, of Halleck. Mr. McGee informs me that the developments are excellent. There are several other claims which are said to be valuable, prospectively, as among others, those owned by Messrs. Atwood. But we want capital—money to make money. The Oro Grande Quartz mill has been idle since last May; its last work was on old tailings from the King mine of your mining metropolis. Mr. W. K. Aldersley, the former able and go-ahead manager, is here again in charge. That the mill will run in the early future, I do not believe; freight charges are too heavy to transport ore from Calico or Providence, while there is not enough ore available here as yet to justify the mill in recommending work.

Plutarch.—Calico Print, May 22: This old mine of McBride & Miller is leased by Thede & Holberg, of Daggett, who have three men at work under the foremanship of John McBride. The shaft is down 100 feet, and a drift is being rapidly driven in from the bottom of the same, also a drift from the 50-foot level which is in 25 feet. There are about 10 tons of 20-ounce ore on the dump taken from the shaft.

Silver Joker.—This mine was formerly known as the Golconda, and is owned by a Los Angeles party and A. M. Rickert. They have one man at work cleaning and fixing the mine in good working order and also mining a drift to the southwest, which is in about 35 feet. The shaft shows plenty of fine ore, and is down about 15 feet. There is about a ton of closely-assorted ore on the dump. Mr. Rickert feels confident of having a first-class mine and will put on a few more men in a short time.

Blackfoot.—The different parties that had leases on this mine had to quit work on account of their lease expiring on the 15th inst., which they could not get renewed. Waterman & Porter having bonded the mine, so it is rumored, and have put 8 men at work and run a tunnel 100 feet and tapped the place where McBride & Miller had their lease, and are taking out considerable good ore. They expect to put on 25 more men by the 25th of this month, which will make quite a force. Messrs. Waterman & Porter are good mining operators, and when they take hold of a mine it is because they have indisputable evidence that it is a paying proposition. The thorough knowledge they have of mining, from years of careful experience, enables them to manage the properties, which they invest in most successfully and profitably. The Blackfoot will undoubtedly be the scene of lively operations in the near future.

San Houston No. 1.—This mine is leased by Mr. Thos. Meredith, the son of one of the principal owners, who resides in Los Angeles. There are three men at work in the 100-foot tunnel, taking out about half a ton of very good rock each day. There are about three tons of good ore on the dump at present. He shipped six tons of 80-ounce ore to Thede & Holberg's mill at Daggett last week. A. M. Rickert is taking out some very good ore on the Mountain Brow. Dan Edwards is sinking a shaft in a large cliff or projecting rock on the Oregon mine, and has struck some rich ore in a seam which appears to widen as depth is attained. H. M. Hasbrouck is taking out some very rich ore from an opening in the Bismarck at a depth of 50 feet. He has a very curious specimen from the place where he is working, consisting of the roots of a plant covered with horn silver. Ed. Mulcahy, John McDonald and several others have leases on the Red Cloud, near the King mine, and are making a lively scene chloriding on that claim. They seem to be in good spirits over what ore they have in sight. J. B. Whitfield is chloriding on the Oriental, adjoining the Bismarck. A. Barber has a small force of men at work on the Silver Reef, adjoining the Waterloo in West Calico. The following are from our Daggett correspondent: Fred Clark was in town last Wednesday, and says that he has three carloads of first-class ore at Lava station from the Lava Bed district ready for shipment to the mill at this place for reduction. The mine is still looking "way up." Robert Moore, of Santa Cruz, Monterey county, in company with Henry Lake, has returned from Soda lake. Mr. Moore is largely interested in that region, and is well pleased with his investments, having purchased further interests in the district.

Sierra.

Alaska.—Grass Valley Union, May 20: At Pike City, the Alaska is working 150 men directly in the mine, besides a large force of wood men, etc. The water which at the 500-foot level covered the lower pump is now in fork, and the pump in working condition. This is the wettest mine on the coast—90 inches of water is pumped, and as depth is attained the flow increases. The present new pumps can raise 150 inches at their final capacity. The company is having made the largest system of mining pumps in the world; when these are in position they can cope with an unlimited quantity of water.

Forest City.—Mt. Messenger, May 15: There is a good opening for first class miners at Forest City. Bunker Hill Gold Mining Company, at Bunker Hill, in which H. J. Redmond, of Forest, is interested, eight and one-half miles east of Forest City, are running an air drift. They have obtained a good prospect and will resume work as soon as the air tunnel is completed. Length of main tunnel, 700 feet. The Extension and Bald Mountain Companies are working quite a number of men, and yielding fair cleanups of gold. The Extension have commenced cleaning up their creek. A small gold nugget was found, the other day, sticking out of the gravel near the boulders. Supt. Colman, of the Ruby, is busily opening out on his upper lead, 16 feet above the deep channel. The gravel mostly cemented, that

requires blasting, has been followed 150 feet westward, where the bed-rock is pitching; and to the east, 100 feet. Width of lead still uncertain. Gravel averages fair pay. As an old miner remarked: "This is a curious country. One oftentimes hardly realizes where he is, or what should be done to most advantageously progress in developing these ancient and lava-capped rivers, seamed with gold." An incline may, in time, be put down to work the deep channel. The main tunnel is about 3000 feet long, and in excellent order, requiring but little repairs. Under the able supervision of Mr. Colman, this mining property bids fair to become one of the most remunerative in the county.

Shasta.

IGO.—Cor. Republican Free Press, May 22: The mines in South Fork district, as I understand, are progressing as well as could be expected, considering the unfavorable weather which has prevailed. A new stamp-mill is at Anderson, which will be put up by Capt. Atkins as soon as the roads are in a condition to haul the same. Several arastras are kept constantly running on good ore.

Siskiyou.

CLEANUP.—Yreka Union, May 21: Johnny Carroll, of Quartz valley, cleaned up a 100-ton crushing last week, realizing something over \$500. Mr. Carroll will abandon the ledge he has been working, and will shortly begin operations on another which pays \$200 a ton.

ETNA.—Si. Jordan is working a quartz ledge which prospects well, and is running an arastra. China claim piping below Summerville and doing well. Supt. Spooner is working 20 bands at Spoonerville, and is getting off five or six acres per season, 15 to 20 feet of bank, and looks for a big cleanup, having taken out over \$10,000 this season. Two miles above Smith, Campbell and Spooner are running another hydraulic claim which prospects well, and expect a big cleanup. All of them are in good spirits, especially the shareholders. Black Bear is working about 25 men; mill not running at present. John Daggett is running on a new prospect where Black Bear was first struck. Present outlook good, dumps are being filled up with quartz, prospects of June cleanup very good, rock in sight as good as \$100 a ton.

Trinity.

MINING MACHINERY.—Trinity Journal, May 22: Major Toms, of New River, passed through here this week on his way home from San Francisco. He informs us that while in the city he purchased an engine, boiler and Kendall mill, which will be shipped to White Rock via Callahan ranch; also that arrangements were made for a five-stamp mill, amalgamating pan and other machinery, which will be shipped as soon as it can be prepared. The necessity of packing machinery on mule-back to the mines compels it to be made up in smaller pieces than if wagon transportation were possible. Major Toms has great faith in the New River mines, and regards a wagon-road from Weaver's as an important necessity. Bullychoop district is active. New machinery is arriving there and development on the quartz mines is progressing. We shall expect a full report from that section soon.

LOOKING WELL.—Late advices from East Fork report the quartz mines of that new district as showing up well, and confidence is felt in their permanence and good paying qualities. Deadwood is turning out bullion in large quantities and with the utmost regularity. It has become so common to hear of large cleanups at the Brown Bear and McDonald mills, as also at Gibson's and others, that it is no longer considered a matter of news.

A RICH PIECE.—On Wednesday morning, while Frank Portillo's boy was looking over the dump of Portillo & Valencia's mine on West Weaver, the little fellow picked up a piece of quartz and gold which is very rich. The piece weighs 2½ ounces in all, of which not less than an ounce and a half is gold. The quartz is rough and certainly could not have come any great distance. It was washed from the mine during the season's work, and it is not improbable that other pieces have gone through the flume.

Tuolumne.

BUCHANAN.—Independent, May 22: The Buchanan road is nearly completed, and freight is now hauled to Easton's by big teams, where it is transferred to the mine by lighter conveyances. Some has already gone forward and about 40 tons more is at Oakland for the same destination. Lang and Hampton are negotiating for the sale of their mine to an English company. There will be nothing done on the claim until the sale is consummated, when the new company will proceed to work the mine on a large scale.

NEVADA.

Washoe District.

HALE AND NOCKROSS.—Enterprise, May 22: The crosscutting on the 2500 level at the north end shows the same vein of ore developed at that point some months ago, improved in character and increased in size and quantity, indicating something better in Savage ground which it is bordering upon. Nothing new developed in the explorations above the 3000 level. Rich bunches of ore are met with, but what is required is one of sufficient size to constitute a bonanza. The drift south from the 3000 level, or bottom of the deep winze, is being forwarded to meet the drift which is to be run from the Combination shaft when it shall reach that level.

POTOMAC.—On the 3000 level the diamond drill hole which was started 120 feet north of the face of the main south lateral drift last week had to be discontinued on account of faulty formation of the ore vein, clay clogging the drill and cross seams, twisting it almost to the breaking point. It only penetrated about 25 feet, and day before yesterday it was started a short distance from the other in the same crossheader. It is now in about 40 feet, and with good luck will soon enter, and pass through the main ore vein, which is demonstrated to lie on the east side of this drift. No water has yet been encountered in either of the three drill holes.

CHOLLAR.—Excellent progress is being made sinking the Combination shaft deeper, 25 feet additional depth having been made at seven o'clock last evening. The formation is more favorable for sinking than was that of the last section, sunk a few months ago, the bottom having passed through the east clay wall into the regular vein matter itself.

This is, of course, owing to the regular dip—about 45 degrees—of the vein to the eastward. Only 20 feet further will carry it to the 3200 level, after which a sum of 30 feet will have to be sunk, and a station will be opened forthwith for a drift to connect with the drift coming from the Hale and Norcross deep winze on that level. When this shaft reaches the 3200 level its bottom will probably be in ore.

CON. CALIFORNIA AND VIRGINIA.—The daily yield has been increased to over 400 tons, and the assays from battery samples at the mills show an increase of value to about \$17 per ton, being an increase of \$5 per ton over the previous week. The exploration and development work on the 1400 and 1600 levels makes excellent progress, the southwest drift on the 1400 having been carried to its connection with the old stopes; 851 feet is the total length of this drift from the main west drift.

SAVAGE.—The drift south from the 600 level of the Gould and Curry is now about 60 feet into Savage ground, and making good progress toward the main shaft of the mine. It is all the way in good vein matter, principally quartz, carrying considerable mineral. Some of it might be found to pay, by careful selection, but the main object at present is to run through to a connection with the shaft of the mine.

ALTA.—On account of bad air the crosscuts west on the 700 level had to be discontinued for the present and all work is concentrated upon making connection with the old Lady Washington, which will give all requisite air circulation. About 100 feet has to be run in order to make this connection.

BEST AND BELCHER.—The pumps are working well and effectively, the further reduction of the water being resumed three days ago. Sixty-two feet more water remains to be pumped out in order to reach the bottom of the shaft, or 2319 level, which corresponds with the 2500 level of the C. and C. shaft.

GOULD AND CURRY.—The upraise above the 600 level, at the Savage line, is now up 103 feet, and continues in low-grade ore. The crosscuts east and west from the upraise, 45 feet above the track floor of the 600 level, still continue in low-grade ore.

YELLOW JACKET.—About 140 tons continues to be the daily yield from the old low-grade workings above the 1300 level. Meanwhile, good exploration work is being done in opening up further resources.

SIERRA NEVADA.—West crosscut No. 2 on the 520 level has been extended 34 feet, making a total length of 541 feet. Formation, hard quartzite and vein schist.

CROWN POINT AND BELCHER.—Nothing new to mention beyond the regular progress of ore extraction and milling. Daily yield, about 375 tons.

MONTE CRISTO.—The drift west from the new shaft, 150 level, continues in very hard rock and makes slow advancement.

OPHK.—The usual progress is being made in the explorations on the 400 level, with no new features to mention.

KENTUCK.—The old workings hold out finely, and continue their regular daily yield of about 60 tons per day.

Central District.

VALUABLE.—*Silver State*, May 22: Charley Wright, just up from Central district, reports that the Locomotive mine, owned by J. F. Clark, is proving to be valuable property. The ore is shipped to Salt Lake for reduction, and averages 332 ounces of silver per ton. The mine looks better than ever before, and there is a large quantity of ore in sight.

Eureka District.

ORE SHIPMENTS.—*Sentinel*, May 22: During the past week ore shipments were made from the mines of the district to the two reduction works in town as follows: To the Eureka Con. works—Ernst and Esser mine, 11½ tons; Marguerita, 13; Seventy-six, 3½; Hecla, 1; Last Chance, 3; Silver Lick, 5; Dunderberg, 15; Lord Byron, 10½; Alexandria, 3½; Lizzie L., 18; Norris, ½. To the Richmond works—Mt. Hope mine, 60 tons; Hannan, 1; Atlas, 2; Centennial, 8; Frazier and Molino, 9; Jackson, 63.

Garfield District.

PROSPECTS.—*Hawthorne Bulletin*, May 20: Since the splendid discoveries in the Hendly mine, the excitement over the prospects of Garfield district is greater than ever. All claims there have a real or a prospective value, and there is every probability that capitalists, encouraged by the results of Farrington's mines and the Hendly, will develop many more valuable mines. The district contains the richest silver ores to be found anywhere, and the permanence of the ledges having been established, investors will no longer fear to venture their means, and many years of active, vigorous prosperity are certainly in the future of the camp.

Grantsville District.

TO START UP.—*Reese River Reveille*, May 22: We learn from the driver of the Grantsville stage that Superintendent Kuchell has just arrived at that place from New York, and that arrangements have been made to start up the mines and mill of the company operating there. The mill is a 40 stamp with a White furnace for roasting purposes. The property has not been in operation since '81, when M. San Pedro sold out his interest for \$70,000. The ore in the mine is of low grade for this section—\$35 per ton, but so large is the space between walls that it is said that 10 men could furnish ore sufficient for the stamps. Grantsville is 65 miles from this point by stage, nearly due south on the edge of Lone Valley.

ARIZONA.

SILVER.—*Prescott Courier*, May 22: Frank Altiers keeps right along taking rich silver ore out of the Catocin mine. He is making another 10-ton shipment. A leaky battery at the Groom creek mill has somewhat retarded crushing. Three concentrators are in place and a carload of concentrates will be shipped in a day or two. Mr. Gray puts the value of these concentrates at \$125 per ton, gold. The Del Pasco mill people are doing right well. Ore crushed by them has never paid less than \$50 a ton, free gold. Dr. Farnham is gaining gold by arastrating on Upper Lynx creek.

COLORADO.

IDAHO SPRINGS.—*News*, May 20: Work goes on night and day at the Plutus Co.'s properties. The ore-house dumps and mills are full of good ore. Sunday is like any other day—no cessation of work. The mill for concentrating the ore runs day and night by water power, and treats about 30 tons every 24 hours. The drifts, stopes and all the openings in the mine show ore; in fact, with the exception of the Freeland, we know of no mine in the State that shows more continuous ore bodies. A large number are working their mines on Trail creek. On Fall river, quite a large amount of work is being done by different parties. The Freeland looks well throughout all its workings, and is producing its usual large quantities of ore. The monthly output foots up nearly \$30,000. The Donaldson, under lease to Ben D. Allen, of Mathews & Webb's sampler, is producing large quantities of good ore, and the lessees are making big money. This and the Champion belong to the English company. At the head of Russell a large number are working their mines. The Bird Eagle lode, Virginia Canyon, which is being worked by Denver parties, is shipping a hundred tons of ore to the concentrator. Saturday last a carload of first-class ore was shipped. The miners of Ute Creek are experiencing considerable difficulty in taking care of the water—the snow, melting rapidly, makes it up-hill work without machinery, although a number are working in drifts and holding the water down. The Argo folks have quit sinking until they get their machinery up. They are shipping big quantities of good ore from the drifts and stopes. Johnson, Young & Co., working the Wallace lode under lease, are drowned out for the present, being unable to handle the water with a whim.

IDAHO.

AT QUARTZBURG.—*Idaho World*, May 22: We have heard it said that two men at work in the Pioneer mine at Quartzburg, and owned by the Gold Hill Company, get out ore as fast as the 25-stamp mill, with the aid of a rock-breaker, can crush it. Don't know whether two men on a shift was meant or whether two men during the day get out enough rock to keep the mill crushing day and night. No matter which, the ore is taken out with but little labor. The reason of it is they have a mammoth mine, and it all pays. Dick Cunningham has run about 50 feet on his prospect, the Cleveland, in Garbrius district, and is now, with the assistance of Wm. Tucker, taking out ore, at the depth of about 50 feet, from a pay vein about a foot thick. The walls of the ledge are about 30 feet apart, and it is estimated that taking the entire ledge, the ore will mill from \$10 to \$12 per ton. Although this is good ore, it would not pay to haul it to the mill—the Forest King—which will make a crushing of the higher grade. They now have out about 15 tons. Dick will soon have a crushing made. The Cleveland has not been sufficiently developed to be classed as a mine, but it is at least a very encouraging prospect; and if it continues as it is now, it will prove to be a very valuable piece of mining property.

CEUR D'ALENE NOTES.—*Record*, May 5: Hoffman & Co. have been obtaining good pay on No. 3, in Cougar gulch, but will soon have to stop work on account of a scarcity of water. Dan McCusker and partners have two shifts engaged in piping on their claim between Gold Run and Cougar gulches. No clean-ups have yet been made. The owners of the Webfoot claim in Dream Gulch expect to make a clean-up to-day. They have had but one before this spring, their operations having been considerably retarded by lack of water. The largest clean-up from a single run on any North Side claim this season was that made last Friday in Dry Gulch, when something over \$1,200 was obtained from a run of eleven days, two additional days being required to clean up. Vestal & Co., who have leased the Badger claim, are pushing piping operations with two shifts. The claim is being managed by Nate Vestal and Dan McGrath. All the machinery is now in place at the Golden King mill, and it is expected that it will be in operation by the first of next week—as soon as the link chain for the drier arrives, and it will probably be in by express the latter part of this week. Should it be delayed longer, it is not unlikely that the mill may be started up Saturday and some quartz run through without the aid of the drier. J. G. Chapman, who owns the arastra in Pritchard gulch, opposite the mouth of Dream gulch, will begin operations to-day on ore from the Gold Hunter mine, lying just above the old wash, and owned by John Hoffman. Mr. Chapman is satisfied that he will be able to obtain satisfactory results from the Gold Hunter ore which he expects to work until the completion of the road to the Buckeye Boy mine renders it possible to get ore down from there economically.

MONTANA.

BUTTE.—*Miner*, May 20: Renewed activity all along the line of Butte's mines and mills is the cheerful report of the *Miner* to its patrons this week. The brakemen's strike suddenly collapsed last Sunday, and during the week the Anaconda mine and smelter resumed operations, and are again resounding with the hum of industry. Several new prospects have been opened up since our last report, and the Bluebird Company commenced the erection of their new mill, which will be one of the most complete establishments of its kind in the West. As a whole, the situation is satisfactory.

THE MARIA.—This mine is located about one-half mile north of the Alice, and is owned by Moore Brothers. The shaft of the mine is down 180 feet, from which two levels have been run. During the past week some fine ore has been struck in the east drift.

THE ELM ORLU.—During the past week the hanging wall has been encountered in the large ore body exposed, and it takes three sets of timbers to go through the vein, which is over 18 feet in thickness.

THE LEONA.—A fine body of ore, two feet in thickness, is now in the bottom of the shaft, which assays from \$20 to \$50 in gold. The ore is free milling, and as soon as the stopes are opened out the mine will, no doubt, take its rank as a fine ore-producer.

THE MARGARET ANN.—This mine is located north of the Moulton. Preparations are now being made to hoist the water out of the shaft. In connection with this property is a fine stamp mill, which is new and in first-class order. The present management will no doubt work this excellent property to its full capacity.

CLARK'S COLUSA.—This mine is now producing from 40 to 50 tons of fine copper ore, part of which is placed on the dump for a reserve, as there is now more than enough ore in sight to keep the smelter going for the next two years to come.

THE GOLD FLINT.—This mine had been lying idle about two years when Ed Rodda *et al.* leased it from the owners, Messrs. Clark & Leggett. The lessees removed the water, retimbered the mine, and are now shipping ore to the Moulton mill for treatment.

NOTES.—The shaft of the Alice has been thoroughly retimbered to the 1000-foot level. The Magna Charta is supplying its average quota of ore, and keeps the Alice mill running constantly. Reports from Telegraph Gulch are encouraging. Some very rich gold float has been found, and several prospecting parties are now searching for the lode. In the Three-mile district during the past week some fine discoveries have been made, and it is expected that some rich strikes will be reported during the summer. The Snowdrift, the Harkaway, the Gregory and the Silver Lick, northwest of the Moulton and adjoining the Samanthia, have lately been leased to a syndicate, who have ample capital to work these mines. It is said that operations will commence in good earnest during the present week.

BOYLE MOUNTAIN.—Boyle Mountain, at the head of Warm Springs creek, out toward Smoky, about 15 miles west of Ketchum, is fairly alive with mines and all glittering with ore. In the Sunday mine, adjoining the Ontario of the Boston Company, James Doran and Charles Love began work on a lease last November. In January they began shipping, and in four months they extracted 25 tons of ore, which netted them over \$2,000. The Ontario old workings were leased, December 20, 1885, to Hugh Condon, Andy Nelson, Jim Carrick and Tom Jones. They have extracted about 32 tons of ore, and are still shipping. They will realize handsomely for their work. The Irvine group, under lease to Mike Carey and Ike Habishaw, netted a couple of thousands last summer. In December, another body of ore was struck. The leasers worked 12 men all winter until March 1st, when they cleaned up about \$5,000. In the Tea Broeck, Doc Raymond, Frank Fulford and Mike Carey worked three men all winter and five toward spring. They took out 30 tons of ore that will net about \$2,000 over expenses. This ore will be brought in right along until cleaned up. The Black Horse, adjoining the Ontario, shipped 15 tons lately.

UTAH.

SANDSTONE MINING MATTERS.—*Southern Utah Times*, May 8: Hartman & Co. have about 100 tons of first and second class ore on the Annie ready for shipment. Tecumseh Hill is dotted all over with chlorides and considerable high grade ore is coming to the surface. Dick Jarman has about twelve tons of fair grade ore on the Steel & Lamb, ready for shipment to the River mill. Kimple & Louis are still working the Leeds mine on a lease; they have out in the neighborhood of 500 tons of ore and are waiting the action of the Leathers, prior to shipment. The California and Stormy King are producing their usual quota of ore, and from present indications the ore bodies are assuming larger proportions than ever yet shown. The force on the Thompson has been increased, all working on ore. The new strike continues to pan out beautifully. In a few hours after the rich ledge was uncovered, enough ore was taken out to yield on George L. Harding's newly acquired fourth interest in the Silver Gate mine several hundred dollars more than enough to pay for that interest. It is a splendid property. Bales, Holling & Harding have 300 feet of stoping ground from the point of discovery to the apex of the White Reef.

REVIEW.—*Salt Lake Tribune*, May 15: The warm season does not come on as swiftly as was expected, the air being kept cool by the great bodies of snow in the hills. But the canyon roads are getting better, and ore is coming in freely. The receipts in this city for the week ending May 12th, inclusive, were \$190,476.22, of which \$109,577.30 was bullion and \$80,898.92 was ore—a very large receipt, indeed, of the latter. For the week previous the receipts were \$123,775.49 of bullion and \$28,327.01 of ore—a total of \$152,102.50. The output of the Ontario for the week was 24,371.34 ounces of fine bullion and \$19,685.22 of ore. The Daly produced during the week 982.44 ounces of fine bullion; no ore. All goes well with this property. The week's receipts of base bullion were \$12,270; of fine bars, as reported, \$24,570, evidently not reckoning in the Daly. The Hanauer smelter produced for the week \$25,880 in bullion; the Germania, seven cars, \$15,766.79. The smelters are now receiving full supplies of ore. The Stormont shipped up on the 6th, of fine silver, \$1820. The Horn Silver, at Frisco, is said to have struck an exceedingly rich streak of beautiful ruby and horn silver ore, worth \$3000 per ton, but the extent of it is not given. The Horn Silver has shipped and sold 650 tons of good ore since the resumption of shipments, about six weeks ago.

REVIEW.—*Salt Lake Tribune*, May 22: The roads are getting dry, the snowline creeps higher and higher on the hills, and streams are full from the melting snows. The receipts of ore by the smelters in this valley are at the maximum, and the ore begin to come in from Nevada and other camps freely. The receipts of bullion in this city for the week ending May 19th, inclusive, were \$103,636.48; of ore, \$53,897.60; a total of \$157,534.08. For the week before the total receipts were \$190,476.22, of which \$109,577.30 was bullion and \$80,898.92 was ore. The Ontario bullion product for the week was 29,988.44 ounces of fine bars, and \$18,834.73 ore sales. The Daly output for the week was 10,377.24 ounces of bullion and \$531.45 in ore sales. Base bullion receipts for the week were \$13,950; fine bars, as per current reports, \$29,090. The output of the Hanauer for the week was \$16,800 in bullion; of the Germania, eight cars, \$17,720.06. The Stormont sent up \$3,200 in silver bars.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific States.

From the official report of U. S. Patents in DEWEY & Co.'s Patent Office Library, 252 Market St., S. F.

New York Metal Market.

Telegraphic advices dated May 27th, give the following New York prices:

- BORAX—6½¢ @ 7½¢.
- BAR SILVER—\$99¼ per oz.
- COPPER-LAKE—\$11.37½.
- IRON—No. 1, \$17 @ 18.50; No. 2, \$15 @ 16.50.
- LEAD—\$4.85 @ 4.95.
- QUICKSILVER—43 @ 43½¢ per lb.
- The following is the latest from the "New York Metal Market Report":
- COPPER—Steady; Lake offered at 10.25 @ 10.55c. Transferable Notices (Lake) offered at 10.80; Transferable Notices (Chili Bars) offered at 14.50.
- LEAD—Steady at 4.80 @ 4.95c. Transferable Notices (Domestic) issued at 4.82½.
- SPELTZ—Steady at 4.40 @ 4.75c. Transferable Notices (Domestic) issued at 4.60c.
- TIN—Quiet at 21.15 @ 21.30c. Transferable Notices issued at 21.25c.
- TIN PLATE—Dull. Transferable Notices issued at 44.45.
- IRON CERTIFICATES—Quiet at \$16 @ \$17½. Transferable notices (May delivery) issued at \$16½.
- SILVER—New York, 99½¢ per oz. London, 45½d.
- MAKER'S PRICES—At tidewater. 100 ton lots of listed irons (when brand is specified) range nominally about as follows: Lehigh, Grade No. 1, \$18 @ 19.50; No. 2, \$16.50 @ 17.50; Grey Forge, \$15.00 @ 16.00. Hudson River, Grade No. 1, \$18 @ 19; No. 2, \$16.50 @ 17.50; Grey Forge \$15.00 @ 16.00. Southern, Grade No. 1, \$18.50 @ 19; No. 2, \$17 @ 17.50; Grey Forge \$15 @ 16.
- Prices generally ruling for metals not regularly dealt in on call at the N. Y. Exchange, covering extremes of buyers' and sellers' views. All prompt delivery.—Australian Tin, May 21st, \$21.20 @ 21.40; Billion Tin, \$21.40 @ 21.60; Banca Tin, \$21.50 @ 21.65; Baltimore Copper, \$9.75 @ 10.00; Orford Copper, \$9.75 @ 10.00; P. S. C. Copper, \$9.75 @ 10.15; Foreign Lead, \$4.75 @ 4.90; Foreign Spelter, 4½ @ 4¾.

THE WASHINGTON TERRITORY coal miners have been on a strike for several weeks, but on Monday of this week those at Newcastle resumed work regularly. Operations at the Franklin mine have not been resumed, and probably will not be for some time. The Franklin miners feel indignant at the manner in which they have been deserted by the Newcastle men. It will be remembered that when the Newcastle strike began the Franklin miners had no grievances and refused to join in the strike until they were persuaded to do so by several hundred Newcastle strikers, who marched to Franklin for that purpose. The Newcastle men have now made terms and returned to work, leaving the Franklin miners, whom they compelled to strike, locked out.

THE Yuma *Sentinel* is responsible for the statement that an old prospector there recently burned a shirt which he had been wearing for some time and the ashes assayed three and a half ounces of gold.

Highland Springs.

Dr. Bates, proprietor of Highland Springs, Lake county, was in San Francisco a few days since. He reports the prospects for the recreation season in Lake county as very promising. The Doctor has everything in good shape about Highland Springs, and is prepared to make the coming season more enjoyable than ever to his numerous guests. Families, and others who wish to seek quiet rest, or the revivifying qualities of some of the best springs in the world, may well consider the superior advantages of Highland Springs and its beautiful surroundings.

TATUM & BOWEN,

25 to 31 MAIN ST., SAN FRANCISCO, and 91 and 93 FRONT ST., PORTLAND, OREGON.

We have recently furnished the Contractors the Machinery for

LA TRINIDAD
(300 Tons per Day)

—AND—

SILVER QUEEN
(100 Tons per Day).

These Mines are Located in Mexico and owned in London.

The Process is the Wet Concentration and the Plants are, without doubt, the most Substantial and Complete ever built.

We are Sole Agents for the Celebrated

ALBANY

Lubricating Compound,
Cylinder and Lubricating
OILS.

We make a Specialty of Lubricants for Export and Home Consumption.

1850. 1885.

RANKIN, BRAYTON & CO.,
...BUILDERS OF...
MINING MACHINERY.

San Francisco: 127 First Street. Chicago: 100 N. Clinton. New York: 145 Broadway.

PLANTS FOR GOLD AND SILVER MILLS, embracing machinery of LATEST DESIGN and MOST IMPROVED construction. We offer our customers the BEST RESULTS OF 35 YEARS' EXPERIENCE in this SPECIAL LINE of work, and are PREPARED to furnish from SAN FRANCISCO or CHICAGO, the MOST APPROVED character of MINING AND REDUCTION MACHINERY, adapted to all grades of ores and SUPERIOR to that of any other make, at the LOWEST POSSIBLE PRICES.

We are also prepared to CONSTRUCT and DELIVER in COMPLETE RUNNING ORDER, in any locality, MILLS, CONCENTRATION WORKS, WATER JACKET SMELTING FURNACES, HOISTING WORKS, PUMPING MACHINERY, ETC., ETC., of any DESIRED CAPACITY.

WATER JACKET SMELTING FURNACES

For COPPER and ARGENTIFEROUS LEAD ores of NEW and ORIGINAL DESIGNS, covered by LETTERS PATENT. No other Furnace CAN COMPARE with these for DURABILITY, and in CAPACITY for uninterrupted work. MORE THAN 150 of them are now RUNNING in various parts of THIS COUNTRY, as well as many in FOREIGN COUNTRIES, giving results NEVER BEFORE ATTAINED as regards CONTINUOUS running, ECONOMY of fuel, AMOUNT and QUALITY of BULLION produced. These CLAIMS have been PROVEN BY RESULTS in ANY NUMBER of INSTANCES, and the GREAT SUPERIORITY of this SYSTEM of smelting ores DEMONSTRATED BEYOND QUESTION. COMPLETE PLANTS furnished to order of any CAPACITY, with ALL IMPROVEMENTS that experience has DEMONSTRATED as VALUABLE in this class of work.

Beyond question the cheapest and most effective machine of the kind now in use adapted to all grades and classes of ores.

This machine has been THOROUGHLY TESTED for the past TWO YEARS, under a GREAT VARIETY of CONDITIONS, giving most EXTRAORDINARY results FAR IN ADVANCE of anything EVER BEFORE REALIZED. A recent COMPETITIVE TEST at the Carlisle Mine in Mexico, showed an ADVANTAGE OF OVER 30 PER CENT in favor of THE DUNCAN. The amount SAVED OVER THE TRUE being sufficient to PAY THE ENTIRE COST of the machines EVERY MONTH OF THE YEAR. One of its MOST VALUABLE features is as an AMALGAMATOR. It saves all THE AMALGAM GOLD and SILVER that ESCAPES the BATTERIES, PANS or SETTLERS, making the machine worth MORE than ITS COST for THIS PURPOSE ALONE.

Baker's Mining Horse Power.

Possessing all the requirements of a first-class hoist and affording means for the continuous operation of a Pump or Blower, without interfering with a hoisting apparatus. It is made entirely of iron, no piece weighs over 300 pounds. At the ordinary speed of a horse, a 1,000-pound bucket of ore may be raised 120 feet per minute. The hoisting-drum is under the complete control of the man of the shaft, and is capable of carrying 500 feet of five-eighths steel rope. SEND FOR CIRCULAR.

SEND FOR CIRCULAR.

IMPORTANT TO GOLD MINERS! SILVER-PLATED AMALGAMATING PLATES FOR SAVING GOLD

IN QUARTZ, GRAVEL AND PLACER MINING.

Warranted the Best Made, Durable and Satisfactory. Full weight of silver and best quality of plating guaranteed. BEST SOFT LAKE SUPERIOR COPPER USED.

3000 Orders filled. References first class. Prices the very lowest. Have received every Medal awarded on the Pacific Coast for Mining Plates. Old Mining Plates Bought, Replated, or Gold Separated.

SAN FRANCISCO GOLD, SILVER and NICKEL PLATING WORKS, 653 & 655 Mission St., San Francisco.
E. G. DENNISTON, Proprietor.

These Plates can also be procured of JOHN TAYLOR & CO., Dealers in Assayers' and Mining Material, 112 to 118 Pine St.

NOTICE.—Mining men are cautioned against purchasing inferior quality of Silver-Plated Mining Plates now being manufactured in this city. There has been a general complaint by purchasers that these plates proved defective in plating and short in weight of silver, assays showing great deficiency in silver guaranteed. Thin, light plating looks the same as heavy, but has no durability. Good plates can be furnished at same price these poor plates cost.

THE FOOS MANUFACTURING CO., - - Springfield, Ohio

THE JENKINS STANDARD PACKING

IS ACKNOWLEDGED BY USERS AS THE BEST in the world. Unlike all other Packings, the Jenkins Standard Packing can be made any thickness desired in a joint by placing two or as many thicknesses together as desired, and following up joint, it vulcanizes in place and becomes a metal of itself (it is frequently called Jenkins Metal), and will last for years, as it does not rot or burn out. Avoid all imitations, as a good article is always subject to cheap imitations. The genuine has stamped on every sheet "Jenkins Standard Packing," and is for sale by the Trade generally.

114-118 Pine Street, - San Francisco.

We would call the attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our full stock of Balances, Furnaces, Mullers, Crucibles, Scorifiers, etc., including, also, a full stock of Chemicals.

Having been engaged in furnishing these supplies since the first discovery of mines on the Pacific Coast, we feel confident from our experience we can well suit the demand for these goods, both as to quality and price. Our New Illustrated Catalogue, with prices, will be sent on application.

For Our Gold and Silver Tables, showing the value ounce Troy at different degrees of fineness, and valuable tables for computation of assays in grains and grammes, will be sent free upon application. Agents for the Patent Plumbago Crucible Co., London, England. Also for E. G. DENNISTON'S Silver Plated Amalgam Plates. The plates of this well-known manufacturer are thoroughly reliable, and full weight of Silver guaranteed. Orders taken at his lowest prices.

JOHN TAYLOR & CO.

CALIFORNIA ARTIFICIAL STONE PAVING CO.

(SCHILLINGER'S PATENT.)

—FOR—

SIDEWALKS, GARDEN WALKS, CORRIDORS, OFFICES, CARRIAGE DRIVES, STABLES and CELLAR FLOORS, KITCHENS, Etc.

The Courts here and in the East have decided that Artificial Stone Pavements with plastic concrete and in detached blocks, are infringements on the Schillinger Patent; and also, that when the plastic material is blocked off with a trowel and cut through far enough to control the cracking caused by shrinkage, that such pavement is in law the same as if laid in detached blocks, and is an infringement of the patent. All property-owners having such pavements laid without the license of the above Company, will be prosecuted.

OFFICE, 404 MONTGOMERY STREET, SAN FRANCISCO.

EOBERT JUDSON, President.

ALBERT H. REICHLING, Secretary.

G. GOODMAN, Manager

THE PEOPLE'S CYCLOPEDIA

Is the Best in the World for General Use.

NEW THREE-VOLUME EDITION NOW READY.

Comprehensive and compact—58,000 topics. Complete in three convenient volumes. Reliable.—400 first-class contributors.

Free.—Brought down to the present year.

Mining Share Market.

The situation on the Comstock, upon which the local mining stock market depends, is not such as to raise prices to any degree. The expected developments in the middle mines have not panned out anything yet. A large amount of low-grade ore is developed and exposed, 300 or 400 tons of which, from the lowest levels, are hoisted to the surface and await milling facilities. The deep explorations in Hale and Norcross have developed and exposed a heavy vein or extensive deposit of ore. The same vein was found on the 2600 level, and it has been followed continuously ever since. There is reason to believe that the 3200 level of the middle mines, now commencing to be opened, will prove to be the bonanza level. It will certainly be more thoroughly explored than the levels above have been.

Nothing tangibly interesting has been as yet developed by the diamond drill explorations on the 3200 level of Potosi, or in the commencement investigations of the 600 level of Savage, neither in the Gould and Curry 600-level openings. The drainage of the Osibston shaft is rapidly arriving at completion, and deeper sinking will soon be in order.

THE city of Chico allows no barbed wire fencing within its limits.

THE largest stock of pebbles in the city only at Muller's, 135 Montgomery St., near Bush. x

Bullion Shipments.

We quote shipments since our last, and shall be pleased to receive further reports:

Alice, May 15, \$22,496; Moulton, 15, \$12,542; Lexington, 15, \$39,232; Silver Bow, 22, \$15,888; Odessa mill, 22, \$4,000; Holberg & Thede, 23, \$4,100; Oro Grande mill, 23, \$5,350; Germania, 18, \$4,262; Hanauer, 18, \$11,350; Queen of the Hills, 18, \$1,200; Alice, 20, \$10,852; Germania, 20, \$2,306; Hanauer, 20, \$2,630; Queen of the Hills, 20, \$1,150; Stormont, 20, \$2,630; Germania, 21, \$2,360; Hanauer, 21, \$2,610; Queen of the Hills, 21, \$1,150; Hanauer, 23, \$2,865; Nevada ore, 22, \$3,541; Hanauer, 23, \$2,865; Germania, 23, \$2,376. During the week ending Saturday, May 22d, there was shipped from Salt Lake City 26 cars of bullion, 641,219 pounds; 16 cars of iron slag, 415,990 pounds, and 17 cars of ore, 511,580 pounds, making 59 cars, aggregating 1,268,799 pounds.

JAMES LEFFEL'S Mining Turbine Water Wheel.

These Wheels are designed for all purposes where limited quantities of water and high heads are utilized, and are guaranteed to give more power with less water than any other wheel made. Being placed on horizontal shaft, the power is transmitted direct to shafting by belts, dispensing with gearing.
Estimates furnished on application for wheels specially built and adapted in capacity to suit any particular case.

Further information can be obtained of this form of construction, as well as the ordinary Vertical Turbines for Wooden Penstocks and in Iron Globe Cases, free of cost, by applying to the manufacturers,

JENKINS PATENT VALVES.

Gate, Globe, Angle, Check and Safety.

Manufactured of BEST STEAM METAL. We claim the following advantages over all other Valves and Gauge Cocks now in use:

1. A perfectly tight Valve under any and all pressures of steam, oils or gases.
 2. Sand or grit of any kind will not injure the seat.
 3. You do not have to take them off to repair them.
 4. They can be repaired by any mechanic in a few minutes.
 5. The elasticity of the Disc allows it to adapt itself to an imperfect surface.
- In Valves having ground or metal seats, should sand or grit get upon the seat it is impossible to make them tight except by regrinding, which is expensive if done by hand, and if done by machine soon wears out the valve, and in most cases they have to be disconnected from the pipes, often costing more than a new valve. The JENKINS Disc used in these Valves is manufactured under our 1880 Patent, and will stand 200 lbs. steam. Sample orders solicited. To avoid imposition, see that Valves are stamped "Jenkins Bros." For sale by

PRACTICAL MACHINIST.

Manufacturer of C. E. Newman's Patent Lone Star Double-Acting Force Pumps. Shoe and Leather, Printers', Paper Makers', Fine, Experimental and Complicated Machinery of every description built and repaired. Estimates furnished for building machinery of all kinds in quantities.

HOOD'S FOUNDRY COKE.

Consumers are respectfully informed that owing to inferior brands of Coke having been sold in this and other countries under the name of "Patent Coke," the Glamorgan Coal Co. (Limited), Cardiff, in May, 1884, abandoned the title of "Patent Foundry Coke," substituting that of "Hood's Foundry Coke."

This Coke is exclusively used by the Selby Smelting and Lead Co., Union Iron Works, Professor Thomas Price, and other consumers here. Large quantities are regularly forwarded to Copper Smelters in Arizona and New Mexico, and also to consumers in Nevada and Salt Lake. The undersigned are the SOLE IMPORTERS of the above Coke, which is for sale in quantities to suit purchasers.

\$1,000 CHALLENGE!

**THE FRUE ORE CONCENTRATOR,
OR VANNING MACHINE.**

PRICE: FIVE HUNDRED AND SEVENTY-FIVE DOLLARS.
(\$575 00), F. O. B.

OVER 1,000 ARE NOW IN USE. Saves from 40 to 100 per cent more than any other Concentrator. Concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order and ready to make tests at the Fulton Iron Works, No. 220 Fremont Street, San Francisco.

As the result of a suit East against an End-Shake Machine (the Embrey), similar to the Triumph, the Frue Vanning Machine Company owns the Embrey patent, and can put in the market an End-Shake Machine of earlier patent that will do as good work as the Triumph, and superior in construction and durability. There will be no risk of suit for infringement.

The Frue Vanning Machine Company warn the public that they claim and will prove the Triumph machine to be an infringement on patents owned by them.

Protected by patents May 4, 1869, Dec. 22 1874, Sept. 2, 1879, April 27, 1880, March 22, 1881, Feb. 20, 1883, Sept. 18, 1883. Patents applied for.

N. B.—We are and have been ready at any time to make a competitive trial against the Triumph, or any other Concentrator for stakes of \$1,000.

ADAMANTINE Shoes, Dies and Crusher Plates

We manufacture the above Adamantine Shoes, Dies and Crusher Plates. They are in use on the hardest quartz in the United States and South and Central America, and have been for the last ten years; we warrant them to out-wear three (3) sets made of any other metal, and many report that they last from 4 to 8 times longer than any other make. They never break AT THE SHANK, and the wear is so light that little or no foreign matter gets mixed with the crushed ore.

Also CHROME CAST STEEL for Mining and General Use, of the finest quality.

The Siphon Centrifugal Pump.

Machinery for Draining Large Tracts.

The San Francisco Tool Company, which has been for some time making a specialty of irrigation and drainage machinery, is now manufacturing a siphon centrifugal pump, combining many advantages over others yet devised for the drainage of large tracts of land. The siphon centrifugal is now adopted in all large reclamation works in Europe, to the almost entire exclusion of the system formerly applied.

Its main features are the connecting of the runner of the pump in a direct manner to the main shaft of the engine, on a level above any possible flood-water; the discharge pipe is conducted over the levee down to a point below the lowest possible low-water mark of the outside stream. No foot or discharge-valves of any kind are used, avoiding all friction otherwise inevitably caused by valves. The pump is charged by means of the vacuum created by the condenser. When the pump is stopped, a water-gate, placed at the discharge of the pump, prevents the outside water from siphoning over the levee into the district; the pump, in the meanwhile, remains charged or primed. For the sake of economy of coal, the use of a compound-condensing engine is recommended. Large hand-plates in the sides of the pump facilitate the examination and cleaning of the runner.

The accompanying engraving represents a 30-inch siphon-centrifugal pump, connected directly to a compound-condensing engine with variable expansion gear, the latter enabling the engineer, without a moment's loss of time, to change the point in the stroke at which the steam is cut off, and to modify the speed and power of the engine as the change of lift or quantity of water desired to be discharged requires.

This engraving was copied from a photograph taken at the moment the engine was ready to leave the works of the Tool Company for shipment. The gate at the discharge, the suction and discharge pipes, are not shown. The relative position of the two steam cylinders, the fly-wheel, heater and jet-condenser, clearly appear; also the connection on the top of the pump with the condenser for the purpose of priming the pump and removing any air which might gather there, by reason of possible leaks or from the air always contained in water. The pipe also furnishes the water for the jet-condenser, which is supplied to it from a point sufficiently high to relieve the condenser pumps of all work of raising it.

The diameter of the fly-wheel is 58 inches; that of the low and high pressure cylinders 14-inch and 26-inch respectively. In this instance

the diameter of the discharge pipe was increased from 30 inches to 40 inches, immediately after leaving the pump, and that of the suction pipes from 23 inches to 28 inches, insuring a small amount of friction (9½ feet per second, discharging the water running through the pipes at a velocity of 38,000 gallons per minute), which arrangement will speedily save in running expenses the slight excess of first cost incurred. The stroke is 18 inches. The number of revolutions is from 130 to 210 per minute, according to the height the water is to be raised or the quantity desired to be discharged under any given circumstances, which can be increased from a minimum of say 10,000 gallons per minute to a maximum of 60,000

third day of February, when all plans, patterns, etc., had yet to be made. The entire plant was in running order on the tenth day of April following. The foundation consists of 50 piles, 40 feet long, driven to the hardpan. We are informed that the entire cost of the plant, including engine-house, two boilers, 16 feet by 90 inches diameter, and foundation, does not exceed \$20,000, for which sum the Tool Co. thinks it can be duplicated. When such a degree of perfection and such results are now attained by a home company which guarantees all its engines, pumps or tools, and their satisfactory condition, it seems foolish to order from the East from people who are not familiar with local conditions, and whose interest

Although the San Francisco Tool Company is prepared to construct pumps of every description, and to fill any order which may be given it, we are informed by the Company that it believes the siphon centrifugal to combine the greatest advantages, and therefore recommends it to their patrons, by reason of the high duty it insures, the permanency of its construction, the economy of first cost of construction and great saving of running expenses and delays effected. Among the notable advantages insured by this system are the following: 1st. The engine and the pump are above the level of flood water, avoiding the danger of the inside water, in case of a break in the levee or excessive rain water ruining the plant

or preventing the running of the pump. 2d. The pump being connected directly to the engine, avoids the use of all gearing and belts, at least a nuisance, and the weakest and most expensive part of any plant, causing constant stops, breakage and expense. 3d. The siphon prevents the pump from at any time raising the water higher than the exact difference between the two water levels, even enabling one to take advantage of the daily changes of the tide-water. 4th. All the working parts of the engine and of the pump are inside the engine-house and above its floor and within easy reach of the engineer, who can, without disturbing

THE SAN FRANCISCO TOOL COMPANY'S SIPHON-CENTRIFUGAL PUMP.

gallons per minute. In practice, of course, actual experience will show which rate of speed will, at a given height, give the most economical results in the consumption of fuel.

This engine has, like all other engines made by this company, received the greatest possible care in its design and workmanship. The working parts are reduced to the fewest number possible without sacrificing its efficiency, and are thoroughly balanced, enabling the makers to guarantee their engines to run at a very high speed. The bearing surfaces are of exceptionally large area, and the lubricating arrangements most perfect. The most of the forged parts are of the best hammered steel, and all the materials used in their construction, as well as the workmanship, are of the best description.

The average of several tests made May 24th and 25th, conducted personally by the agent of the reclamation company, showed its capacity to be 37,907 gallons per minute, at a lift of 11 feet 7 inches, the engine indicating 156 horsepower, with a consumption of 4.4 pounds average Sydney coal per actual horse-power of water raised per hour—the most satisfactory and economical showing so far made by any pumping plant.

This plant was constructed for the drainage of the Pearson Reclamation District, in Sacramento county. The order was received on the

ceases on the delivery of the shipping receipt.

The Pearson Reclamation District is one of the largest and most successful reclamations on this coast. It consists of 8800 acres of very fertile land surrounded by a superb levee of an average height of 18 feet, 15 miles long. During the extraordinary freshets and floods of the winter just past, the pumping plant, formerly constructed by the San Francisco Tool Company, and consisting of two 15-inch pumps, constructed for its drainage, proved entirely insufficient to cope with the large body of rain and seepage water. On the 20th day of April about 2000 acres were covered with water from 6 to 12 inches deep and 350 acres thereof forming the bed of a lake 5 feet 8 inches deep. Notwithstanding the heavy rains in the latter part of April, and the formidable amount of seepage finding its way through the solid earthen embankments, the 30-inch siphon centrifugal has now drained the entire district, all those lands being now covered with growing crops, even the lake bed being cultivated at the time of this writing.

The pump here illustrated and described is at present pumping the water 14 feet (the difference between the inside and outside water levels), while the inside water is 24 feet lower than the top of the pump. No difficulty whatever is experienced in holding the pump full of water by means of the vacuum, at either a high or low speed of the engine.

any other part, adjust any part of the engine and remove either manhole plate or side plate of the pump within two or three minutes. The great delays and expense experienced in cleaning, examining or repairing submerged pumps are thus avoided. 5th. It obviates all earth-work or interference with the levee (always dangerous), and all masonry or hulkheads. 6th. By opening the gate, a means for irrigation during the summer months is furnished, as the outside water will at once be siphoned over the levee into the district, a most important feature for reclamations in California. Mr. P. J. Van Lohen Sels, the agent of the reclamation district, is highly pleased with the operation of the pump, and testifies to its efficiency and the results referred to above.

A CHANGE FOR THE BETTER.—The Paradise Valley ore delivered at the concentrators two weeks ago averaged \$26.60 per ton assay value. Now the superintendent's report shows that for the last week the average assay value of the ore reduced was \$88.90 per ton. This is a decided change for the better, and we doubt if there is a mine in the State that can equal it.—*Silver State.*

WE would advise miners not to be in too high a hurry to rush into Grantsville—work has not been resumed in the mines there yet.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eps.

Lower Springs Mining District, Shasta County.

EDITORS PRESS:—This district lies four miles west of Redding and two miles east of Shasta, and at the present time has a "black eye." Everything in the quartz business is lying dormant. Nevertheless it will come to the front at some future day. This great mining belt extends many miles distant, perhaps the largest mineral belt on the coast. They are all fissure veins, and most of them prospect in free gold. There has not been anything found here yet to excite capitalists. The greatest depth obtained upon these veins is 40 feet, and this depth is very rare. Numerous chimneys have been found. The best portion of this belt lies north and west of Salt creek. All the veins run in an easterly and westerly direction, and pitching north. At Lower Springs is located the White Oak mine, Eastern Star, owned by Mr. White and wife. These are large veins and prospect well in different places, sufficient to cause two different parties to erect a custom mill upon the ground. But they failed on account of being incompetent in the milling business. The gold is very fine here and requires a first-class mill to save the gold, and an experienced millman to run the mill; otherwise they cannot make a success in any mining camp.

Further to the west of these latter mines is Mrs. Myers' group of ledges, running through the large mountains on the north portion of her patented land, then passing through Mrs. Weiser's section of land. I believe there is millions of money hidden in these mountains of veins. The time is coming when a company of means will probably run a tunnel through these mountains, in order to tap these heavy ledges of gold-bearing quartz. Most of these ledges are in a granite formation. This does not hurt them in the least. Some of them are in porphyry, and some in talc slate formation.

One-half mile north is the Muchmore mine, owned by Muchmore brothers. They are working this mine by tunnel and are working about 40 feet below the surface in the tunnel. They have run upon the ledge about 80 feet, and it prospects well the entire distance. It still continues in excellent ore. They have been working their ore by arrastras until recently, and will take out upward of a hundred tons of ore, afterward talking about a mill. The boys are working this ledge in the proper shape, doing good, substantial timbering as they go along. I will not say as much in favor of this mine as I would like to, but will say that I believe many more exist in this district equally as good as the latter mine.

Lower Springs, May 26, 1886. I. C. F.

Is Mining a Trade?

[Written for the Press.]

With the majority of people a miner seems to be of little importance. His occupation is seldom, if ever, dignified by being entitled a trade; any man who has muscle enough to handle a shovel or throw a sledge is popularly considered as competent to mine. A man may be a "botch" as a carpenter, a blacksmith, or a machinist, but if he has worked a few years at either one of these occupations he is said to have a trade. Not so with the man who climbs the rugged mountain-sides tracing the course of mineral veins, or who delves hundreds of feet beneath the earth's crust; and yet his profession calls for as much skill, as much patience, as much time to learn, as much courage, as much intelligence, and more native good judgment, than any other avocation known.

To be a good miner requires a happy blending of theoretical and practical knowledge. The miner who knows nothing but what his observation and his hooks have taught him is not a good miner; the one who knows nothing except that which he has picked up by experience is not a perfect miner. Both these types are one-sided men.

The good miner should have physical strength to begin with. He must have a good eye for color; it is mainly by color that he recognizes copper, lead, and the numerous silver chlorides, and distinguishes one from the other. He must have some knowledge of geology and lithology; he should know how to use the blowpipe and make an assay; he should have an elementary knowledge of chemistry, understand the use of the compass, have a fair knowledge of hydrostatics, be accurate in arithmetic, know how to set up and burn a pit of charcoal, how to temper picks and sharpen drills, keep a set of account books, and be able to hew a stick of timber square to the line. He must know how to run an arrastra, a pan or a stamp battery. He must have a knowledge of the power of steam, and how to take care of a steam boiler. He wants to know what kind of timber lasts the longest underground; how to build a dam in a stream so it will not leak. He must know

the proper grade to give a flume or a ditch, and understand single-hand, double-hand and power drills. He must know how to timber an incline, a shaft or a drift, sink through quicksand, drive through caved ground, or blast through granite hard as the huf of steel. He must know how to stope a vein only six inches thick and catch his ore on canvas, or work an ore body 200 feet wide, if required, by "square sets" and "cribs." He must be able to pack a pump, tie a howline, splice a rope, fry a slapjack and figure out the discount on a bar of bullion.

Thus we see that the miner is not only a miner but a cyclopaedia also, so to speak, being by turns artist, geologist, chemist, blacksmith, carpenter, engineer, machinist, amalgamator, cook, sailor and book-keeper.

Does the miner do us any good? Let us see. Where does the iron come from that makes our wagons, steam engines, boilers, plows, harrows, hoes, sewing machines, knives and forks, down to needles? From the iron ore dug out of the ground by the miner. Whence comes the coal that smelts the iron and propels our steam vessels and warms us? Dug out of the ground by the miner. Where does the clay come from that makes our chinaware, our soup plates and the coffee cups? Gouged out of the pits in the ground by the miner. Where do we get the tin to make our dippers and milkpans, our copper to sheath our ships and make pins, our lead and antimony to make type for the printer, our five-cent nickels to buy beer with, many of our medicines, our paints, our gold and silver jewelry, our gold and silver money, rubies and diamonds that blaze on the person of beautiful woman, and set off the majesty of kings? All, all, discovered and dug out of the ground by the industrious and modest miner—the only man who can get rich without taking it from some one else. We cannot do without our miners. Take the miner away and the world would all be barbarians inside of 50 years.

C. L. LANG.

Correction.

EDITORS PRESS:—In my article in Xanthates, No. 2, I have said: "I conclude that, in the precipitation of copper by an alkaline Xanthate, two molecules of the precipitant are decomposed for one of the copper salts." If the last six words had read "for one of the copper salt produced," it would have been correct, but I am not so dishonest as to pretend that that was what I meant. It was a genuine error. It is evident that two molecules of the copper salt acted on, and two of the precipitant, must mutually decompose, yielding one molecule of copper Xanthate, two of potassium sulphate (or chloride as the case may be), and one of Xanthic acid. A similar erroneous implication in the third paragraph of my article is efficiently corrected by this explanation. C. H. A.

Nogales, May 25, 1886.

BOISE COUNTY MINES.—The Boise county placers are still turning out a good deal of gold annually, but the amount is insignificant as compared to the years from 1864 to 1872. But while the placer ground is being gradually worked out the quartz mines are coming to the front, and the indications are that the yield of precious metals from the quartz mines will in a few years exceed the most famous yield of the Basin. Boise county has many large and rich quartz ledges, and whenever they have been developed they have paid large returns. The Gold Hill mine at Quartzburg illustrates what can be done through energy and perseverance. There are many other leads, doubtless, just as good as the Gold Hill, but they lack development. The Banner mines further illustrate what may be done by thorough development. Here are some of the best mines in the Territory, but until men of pluck and energy took hold of them they were not considered valuable. Boise county is slowly but surely coming to the front and all that is lacking to again make her famous as a producer of precious metals is capital, energy and intelligent labor.—*Idaho Statesman*.

MINING IN SHASTA.—As an evidence that gold quartz mining is profitable, we call attention to the amount of machinery constantly being shipped here. No industry of the county at present is receiving the attention legitimate mining does, and with only one exception, there have been no suspensions in the past year on a gold quartz mine. Aside from the suspensions and failures in our refractory silver ores, the mining record for the past year in this county cannot be excelled by any county in the State, and yet gold quartz mining in old Shasta is in its infancy.—*Democrat*.

MINING LEGISLATION.—Congressman Symes, of Colorado, has introduced a bill in Congress providing that mining claims, hereafter located, shall not exceed 20 acres; but no claim shall be located before a vein or lode has actually been found. The locators of all lode mining claims hereafter made on the public mineral lands of the United States, or their heirs, shall have exclusive possession of all mineral deposits existing within the boundary lines of any claim in a downward direction. No vein is allowed to be followed outside the vertical boundary lines as first established.

Advice to Prospectors.

The Monitor quartz mine, above Columbia, is being opened by Mr. John Neale, assisted by moneyed men in San Francisco, to whom he has given an interest for developing the property. Were his examples followed by others who own property of this description, it would be better for the community and themselves as well. The time has gone by when fancy prices can be obtained for a hole in the ground upon an ancient reputation of "what has been taken out." Buyers prefer to "see" the vein and test it before establishing a mint in an out-of-the-way place as a speculation. It generally results in all "speculation"—no solid results except blasted hopes. Mr. Neale's philosophy is sound. If you have faith in your mine, and think it valuable, show your faith by being willing to take a part of the chance yourself. Put your labor against somebody's coin, who is willing to meet you half-way. To ask one to put all his capital against your guess is hardly reasonable, unless you can show him something beside opinion or theory. Some men have held this kind of property—valuable, undoubtedly—for years, and being undeveloped, the high figures demanded have prevented a sale. They will hold it years longer, many of them, and in the meantime rustle for bread. Get help to develop it, and take your chances with those who assist you. Then, if your mine proves valuable, you share in the success, instead of continuing to hold dead and unproductive property. If it is a failure, you are no worse off than before, except in imagination.

Many men holding claims would to-day be in comfortable circumstances if they had years ago sold at reasonable figures, or given some one of means a chance to show the profit there might be in developing a valuable mine. If the mine turns out rich, the reserved portion may sell for more than, formerly asked for the whole. If worthless, you have robbed no one, but only induced some party to share equally in your mistake. In the one case you improve your finances; in the other, you are helped to bury your dead mine and set yourself free to find a better one. Years ago, before skill claimed partnership in quartz mining, the Monitor was noted for rich rock and a brilliant future. The old story was repeated here, as in hundreds of other instances. Ignorance, water, disagreements, high wages, waste and extravagance hurt the mine. Shafts caved in, timbers decayed, and tunnels collapsed—leaving wreck and ruin behind. It takes coin to go back to old works and make a mine out of a caved hole. This, Mr. Neale wisely realized. Men do not want to buy a reputation when they bargain for a mine. He puts his faith against their don't know, and the outcome will be a mutual benefit to the parties direct and to the community indirectly. Would that there were more miners of Mr. Neale's enterprise and sagacity.—*Tuolumne Independent*.

Our Johnnie's Composition on a Prospector.

A prospector is a allways rich. His mines is the bigest thing out and any other prospector's mines is no akount. He packs rich specimens when he comes to town and no boddy ever hears of a cabin being robbed. He drinks whiskey for soshibility, but he dont like it. He will lokate you in the extenshun of a mine what shows free gold if you lissen to him huz you all nite, and set them up every five minits and giv him 4 bits in the morning to eat on when he aint too thirsty. You can giv him a grub stake and he will go to the mountains, and lokate a township, and if he finds anything good he lokates that himself, and puts you in the fourth suthery extenshun, and comes back for sum more grub with sum more specimens, sais we got the world by the tale, borrows 10 dollars and gits full. He is a generous man and will share his last slise of bakon with a nother prospector when a har-keep is putting up. He sais a man in this kuntry is like a bronko, no akount less hes broke. It makes him russel. Let a prospector sell a clame for 1 hundred dollars, and sleep in clean sheats, and eat pie for too days at a hash stand, he gits despitick, and his old friends what staked him cant git close enuff to hand him a potato on a fish pole. He works hard for a year on his best cleme, and when he gits a expert to go see it, he steps into the hottom of the shaft and sets down on the dump to look at the lege. He asts the expert 2 hundred and 50 thousand dollars for the prosepck, and if the expert wont take it just now and lone him 20 dollars or treat, he says he is a frod and the kuntry is gon in by the dam Chieyeman.—*Bodie Free Press*.

GOLD MINE LITIGATION.—Judge Sawyer, in the United States Circuit Court, has confirmed the findings of Master in Chancery Houghton in the suit brought by the Pioneer Gold Mining Company against B. F. Baker, and involving the ownership of the Pioneer mine in Sierra county. The Master in Chancery found for the defendant in the sum of \$72,000. Judge Sawyer overruled all objections and exceptions to the findings of the Master.

THE experiments with ore concentrators at the Brunswick mill have demonstrated to the satisfaction of the management of the Yellow Jacket mine that ore heretofore considered too low in grade to pay for the cost of reducing it to bullion can be crushed profitably by the new process.

The Tomichi Valley Smelter.

Mr. N. A. Foss, of Gunnison, Colorado, sends us the following clipping from a local paper: A visit to the Tomichi valley smelter these days almost makes one think that they are in Pueblo or Denver. The work has been pushed from the beginning to the present, and aside from the blast furnace, the machinery is nearly ready to perform its work. The great boilers and their furnaces were finished ready for the fire last week, and on Saturday afternoon smoke came from the stack of the engine room for the first time. The fires were kept up all day Sunday for the purpose of drying out the masonry, the boilers carrying about 10 pounds of steam Sunday afternoon. The finishing touches were put on the two large roasters yesterday afternoon, and last night Superintendent Foss ordered fires to be lighted in each of them, which will be kept burning until they begin to feed ore, probably some 10 days hence. This will thoroughly dry the heavy brick walls by a slow, steady heat, and will leave the ovens in fine condition for receiving the high degree of heat that is necessary to accomplish the desired object. The capacity of these roasters will be from six to eight tons per day each, according to the kind of ore that is being treated.

The scarcity of lumber is here again causing delay and annoyance. The heavy tressel-work on the east side of the building would have been completed before this time, but it has been impossible to get the heavy framing timbers which are used in its construction. It was expected, however, that several cars would arrive last night, and if they came the huge framework will be ready to receive the rails within a week. When these are laid, cars can be run to the upper or receiving floor of the building, from which the ore is fed into the crusher and rolls and is sampled. Then, if it requires roasting, it is fed into hoppers on the same floor which conduct it into the roasting ovens. If the ore is not refractory it is dropped through the trap doors into large bins, whence it is wheeled on to the mixing floor and goes to make up its proportion of a charge for the furnace.

The blast furnace, which is said to have a capacity of 40 tons per day, is in course of construction. It is supplied with wrought iron plates and patent tuyeres, and Superintendent Foss thinks it is one of the most perfect furnaces he has ever seen. The material for a second furnace is on the ground and will be put up as soon as there is enough ore on hand to warrant putting it in blast.

A number of carloads of ore have already been received, part of which is in sacks and piled on the receiving floor, the rest being in one of the large bins adjoining the mixing floor. Mr. L. E. Fry is now out in the camps buying ore, and if a sufficient quantity can be delivered here by June 1st, the works will blow in on that day.

Professor Caldwell, the metallurgist, has his laboratory in one of the small houses east of the main building, and a few minutes conversation with the gentleman makes one feel he is thoroughly acquainted with his chosen profession.

The works throughout have an appearance of solidity and perfection which must be reassuring to the miners who visit them, and within a few weeks a large and steady stream of ore will begin to pour in and a rich stream of bullion to pour out.

Petroleum Items.

There is continued and intense excitement in regard to petroleum in Los Angeles and Ventura counties. A company of San Francisco capitalists are prospecting for oil in the Sespe region, while the great Standard Oil Company are very busy in prospecting the oil basins on the rancho of Hammel & Denker and rancho La Brea.

The continued development of oil in La Puente and Petrolia is very gratifying. A well has been recently bored near Santa Paula, in Adams' canyon, Ventura county, that yields 50 barrels per day. Others will be sunk in a short time.

West of this city, on La Brea, the work of sinking oil wells has begun by a Pennsylvania firm in good earnest. Messrs. Hammel & Denker will doubtless sink some wells in a short time on their portion of the oil basin in the rancho Rodeo de Las Aguas. Oil gushes out of the rocks on this great rancho, as it does in some of the hills in this city.

The artesian well of Mr. Ivar A. Weid, in the Cahuenga valley, is flowing water and petroleum, while two wells sunk for water in this city have reached petroleum. On all sides the petroleum boom is spreading.—*Los Angeles Herald*.

A NEW SIXTY STAMP MILL.—There is an undecurrent of news to the effect that the Ontario Company will commence the erection of a new 60 stamp mill here this summer. Mr. R. C. Chambers has been in San Francisco for some weeks, and it is believed he is there giving orders and closing contracts for the necessary machinery. We have known for some months that such an undertaking was in contemplation, and although we have not as yet been able to learn anything about the matter from headquarters, we believe a new mill will be built, and that the proposed site is in the ravine northeasterly from the Crescent concentrator. We hope such will be the case.—*Park Record*.

Washington Territory Mines.

A correspondent of the *Call*, writing from Colville District, W. T., says:

The Colville mining district is the most northerly settlement in this inland empire. The Hudson Bay Company established a trading post on the east side of the Columbia river, 35 miles south of the boundary line, in 1852, and gave it the name of Fort Colville. From this a small river and the surrounding country took the name of Colville, which is still applied to that side of the Columbia river from the Spokane river to our northern boundary. After all disputes between the governments about territory were arranged it became necessary for the Canadians to retain a military station south of the impassable mountain range near the 49th parallel, to supply surveyors and protect other interests from Indian depredations; so Fort Colville was reserved for that purpose and occupied by the British army at a later period than any other post within the present limits of the United States. While this reservation was controlled by Her Majesty's representative it was under the jurisdiction of English military law. It is now considered a part of the public domain, but has never been surveyed and opened to settlement. The buildings stand to-day as they were built 30 years ago. Stock raising is the chief industry, and horses and cattle are sold to drovers who visit the country annually. Means of transportation have never been provided to market agricultural products, and the home demand has been limited, until the rush occasioned by the discovery of the mines.

The mines are in all directions from this town and distributed over a country 30 by 50 miles. Over 400 discoveries have been reported and 350 locations recorded. Silver in paying quantities has been found in geological formations so different from the usual order that experts have passed over rich ores without detecting any trace of mineral. The greater portion of the ore is galena of low grade. The old Dominion mine, near Chewelah, 30 miles south of this place, is the only ledge that has been efficiently developed to estimate the value with any degree of certainty. Its value is well known and undisputed. Large quantities of picked ore have been shipped to smelting works in the Eastern States, and paid handsome profit, notwithstanding the great expense of hauling on wagons to Spokane Falls and shipment at a high rate over the Northern Pacific road. Large bodies of ore are in sight and on the dump, guaranteeing millions to the fortunate owner. The Ella mine, in the same vicinity, prospects well and promises to duplicate the Old Dominion. Machinery is greatly needed to reduce this ore, as it cannot be transported without great expense, as the nearest shipping point is 60 miles distant. The Gold Hill Company has a ten-stamp mill at their mine, 15 miles southeast from this place. Owing to delay in getting some attachments in position they have done no work to date. Many other mines promise as well as these, but have not been sufficiently developed to justify estimates.

Mines are, as a rule, located in rugged mountains. These are in a level country. A high wall of quartz and granite on the eastward blocks the passage of the eager prospector in that direction; but low spurs spread out like wings to the river, and it was on these that croppings were first discovered that have developed into extensive deposits of precious metals. These ledges sometimes pinch out and cannot be traced below the hard cap which overspreads the whole region at a depth of 10 to 25 feet. Failure to trace the veins below this cap has discouraged prospectors who have exhausted their grub stakes and given rise to the belief that these croppings are only floats. This whole country may have been shaken by some commotion that displaced the surface and spoiled the connection where these veins should have been united below the cap that is quite common in quartz-mining districts. Those who possess means and have prosecuted their researches have been eminently successful. Poor men cannot develop quartz ledges in this or any other camp where a shaft must be run at great expense in almost impenetrable geological formations. This class holds the finds in this district. Capital must come from outside parties before prospecting can be done. Men without means should not rush to this or any other undeveloped quartz field. There are hundreds in the camp who cannot get work, and more are coming every day.

On the west side of the Columbia river there is a large Indian reservation. Croppings of rich ore have been discovered in many places within its borders, but no work can be done on that great portion of the public domain withheld for these shiftless tribes. The Government has spent thousands to build mills and furnish wagons and machinery for these Indians, but the richest mines must lie unworked and fine agricultural lands untouched by the plow. Kettle river valley, and the table land near by, would produce wheat enough to feed all the Indians on the coast, and the mines on this reservation would supply silver enough, if worked, to buy their clothing; but this wealth is lost to the world, and those who wander over it are supported in idleness.

The monthly shipments of salt and borax from Rhodoe, Nevada, a station on the C. & C. Railroad, average 400 tons of the former and 50 of the latter.

A Boiler Inspector Wanted.

The following petition has been filed with the clerk of the Board of Supervisors of this city: The undersigned trades, labor and protective organizations of the city and county of San Francisco, with a membership as herein-after stated, respectfully represent and show as follows:

That in March, 1876, the Legislature of this State enacted a statute providing for the appointment of a boiler inspector for this city and county by the Board of Supervisors, and that although ten years have elapsed since its enactment, no attempt has ever been made by any of your predecessors to appoint an inspector as provided, and that since the passage of said act no less than three serious explosions have occurred in this city, entailing a loss of five lives, which explosions your petitioners believe would not have occurred if said inspector had been appointed and the boilers examined by him as required in said statute.

That your petitioners believe that the enforcement of said law is an absolute necessity as a measure of protection to the working classes who are invariably the sufferers by an explosion, and the sufferers in the respect that a demand for repairs which are constantly needed on boilers frequently leads to the discharge of the employee requesting the same. Your petitioners further believe that said statute represents the will of the people, and was enacted by their representatives with the evident intention of its provisions being enforced, its direction being mandatory to your honorable body, and its requirements establish a precedent followed in all large cities throughout the world.

Wherefore your petitioners request that your honorable board will immediately carry out the spirit and interest of said statute by appointing an inspector as provided, or give reasons why such an appointment should not be made.

Signed by the president and secretary of the Marine Engineers' Beneficial Association, Boiler-Makers and Iron Ship Builders' League, Can-Makers' Protective Union, Machinists' Union of California, Pacific Coast Association of Stationary Engineers, Pacific Coast Marine Firemen's Union, Federated Trades and Labor Organization, Harness, Saddle and Collar Makers' Union, Representative Council of the Iron Trade, Coast Seamen's Union, Amalgamated Society of Engineers, International Furniture Workers' Union, Stone Cutters' Union, Journeymen Shipwrights' Union, Musicians' Mutual Protective Association, International Furniture Workers (English speaking branch), Pattern Makers' Union, Bookbinders' Protective and Beneficial Association, Steam-Shipmen's Protective Union, International Cigar-Makers' Union, No. 225; Boot and Shoe Makers' White Labor League, San Francisco Typographical Union, No. 21; Iron Molders' Union, No. 164. Total, 23 unions, representing 8788 members.

Hydraulic Gravel Elevators.

The *Denver Tribune-Republican* says: The hydraulic gravel elevator plant, two miles this side of Golden, on Clear Creek, is now in successful operation, and is well worthy of inspection by all, and especially owners of placer properties. This plant, with cuts illustrating the same, was fully described in the *Tribune-Republican* a few months ago, just as the cold weather necessitated the shutting down of work, and many persons were disappointed in that they could not see it in operation. Now, any one interested in observing how easily and rapidly vast quantities of gravel are elevated into flume boxes 25 feet above bedrock, can take an early train, witness the process for two hours and return to Denver in time for dinner the same day. There is a large area of rich placer ground in Colorado that cannot be profitably worked on account of not having fall sufficient to give dump facilities, and also because the bedrock is so wet that it cannot be reached by ordinary methods of mining. Plants of this character not only elevate the gravel to such height that dump room is created, but also lift surplus water so that operations can be carried on upon bedrock. Colonel Cummings will be glad to have visitors inspect his working at any time, though the pit will, of course, be larger after ten days' or two weeks' more work, and flumes on bedrock will then be in place, carrying the gravel from the faces to the elevator sump, and the visitor have a better opportunity to understand the full significance and scope of this method of working flat and wet placer deposits.

THEY DEMAND GOLD.—A dispatch from New York says: There are many owners at present in New York, said an uptown real estate broker of prominence yesterday, unwilling to sell because they don't want the money. They will sell for gold, but not otherwise. They will not take the money of the country owing to the continuance of silver coinage. They are willing to sell real estate at the present quotation if they can get gold, but not for money not based on a gold standard. There are owners who would rather hold their real estate. If they sell at all, they insist that the mortgages they accept shall have a stipulation to be paid in gold distinctly expressed. The mania is spreading among those who are not bound to sell, and some financial institutions are already entering upon that policy.

The Eight-Hour Movement.

It has been unfortunate, all around, that the active initiation of the eight-hour movement should have occurred just when other phases of the labor question were in a perfect fever of excitement. For two or three years past the question of shorter hours of labor has been under discussion, and during the past winter the movement took definite shape in a demand to be put into execution on the first of May. Had the demand come at a more opportune time, there would have undoubtedly been a much more general acquiescence in the movement. But it happened to come at a time when moderate counsels seemed to have been remanded to the background, and in their stead came a blow intended to terrify into acquiescence. People conscious of their strength can be much more easily coerced into concessions than driven.

The eight-hour movement is quite a different thing from the question of wages. The demand for eight hours' work is chiefly based upon the acknowledged fact of overproduction under the present system of labor, supplemented by the great aid thereto brought about by the introduction of labor-saving machinery. True, there are cases where the hours of labor are excessive—injurious to health—and should be reduced at all events. But the leading motive of the demand for a reduction of the hours of labor is to make room for the employment of the present idle labor of the country. The proposition will reduce the product of the present utilized labor of the country about 20 per cent. The idea of turning out the same amount of work in eight hours that is now done in ten is mere idle talk. The honest leaders in the movement do not pretend that a man is overtasked by ten hours' work. The question of pay is left as a mere local matter, to be settled as the employers and laborers can agree. The greater leisure secured for intellectual culture is chiefly "hush." A few would thus improve their time—more might. In this, as in the movement for an increase of wages, the socialistic element has crowded itself in, to the great disgust of the better portion of the promoters. The red flag should be put down wherever it appears in this country; it has no place in a land where the people rule. Let it be forced back to the place in which it belongs—where the one-man power prevails.

The Effect of the Eight-Hour System.

If it becomes anything like general, will soon show itself in an advance of prices to correspond to the increase of wages which it may induce, if any, in the specialties to which the measure may be applied. It is an almost unquestioned fact that the present rate of wages in general manufacturing industries is as high as the present prices of products will stand. There are very few people accumulating fortunes from manufactures at the present time, except in specialties, where the prices can be controlled by patents, franchises or corners. Statistics show that capital invested in general manufacturing throughout the country does not earn over three and a half per cent, which is not an exorbitant price for the use of money. Hence any increase of wages without a corresponding advance of prices would be ruinous to both the employer and employed. Again, if prices should be advanced, say 15 or 20 per cent, that fact would open the doors to an almost unlimited amount of foreign products, which would proportionately advance the demand for labor, and remand the laborer back to the same position from which he is now striving to emerge.

The question of labor is too complicated a thing to be handled without due care and thought, and just here arises the need for governmental action, under which it can be placed in the hands of wise and discreet men, who should be selected with special reference to their fitness and disposition to act impartially between man and man. Here are some figures bearing upon this phase of the question, which are both interesting and instructing.

The various labor unions of New York city are estimated to comprise an aggregate membership of 130,000. The effect of adopting an eight-hour system of labor in enhancing the prices of many commodities is remarked upon by the *Chicago Tribune*, which says: "There are probably on hand in this country \$1,000,000,000 worth of manufactured goods. The average increase in values will be fully 15 or 20 per cent, corresponding to the enhanced cost of production. This will add from \$150,000,000 to \$200,000,000 to the selling value of the stocks on hand. Sugar has already felt the effect of what is coming. The strike in the great Long Island sugar refineries has put up the cost of refined sugar, at retail 2 cents and at wholesale 1½ cents per pound, or somewhere between \$160,000,000 and \$170,000,000 per annum. If the average advance is but 10 per cent, that adds from \$16,000,000 to \$17,000,000 to the bill, representing that much more profits to the manufacturers to be paid by the consumers. The great bulk of consumption is by the city wage class and the farmers, who together compose nine-tenths of the community; hence they must pay nine-tenths of the increase caused by the eight-hour system. This effect upon sugar is a fair illustration of the general effect, for, as the eight-hour limit is to be demanded in all lines of city production, this result must obtain all through."

Hours of Work in Past Years.

In the early part of this century, in English cotton factories, the week extended to 74 hours; from 1833 it was reduced to 69 hours. From this it went gradually to 60, and in 1874 to 56½ hours, which may be considered the normal working time of the week in Great Britain; altogether there are trades where 50 to 52 hours are the rule. In the United States the extent of the working day in cotton mills was 13 hours in 1840. This was gradually reduced to 11 hours, and since 1883 to 10 hours in Massachusetts, with other States beginning to move in the same direction.

A Word in Favor of Short Hours.

In speaking of the building trade and of the normal working day of eight hours in the latter part of the middle ages, Thorold Rogers says in the interest of short hours: "Employers were very likely to discover that the laborer's resistance to an excessively long day was not entirely personal, and that the work might suffer from the workman's weariness and exhaustion." The excellence of the work, lasting through ages, when more recent constructions have disappeared entirely, is even a more eloquent proof of the soundness of the economic views of our forefathers than the voices which are raised from the grave of yellow parchment. Germany, then at the head of Europe in commerce and manufacture, the economic ruler of the world, the banker and trader of Europe, held to the same rules during its high tide of prosperity, all of which shows that reasonable hours are not at all incompatible with great activity and productiveness; nay, that they are a necessary condition to their achievement.—*Millman and Mechanic*.

Gold Hill, New Mexico.

The merit of the mines of Gold Hill district are attracting the attention of men in search of mines that will pay fair dividends on investments. No property in Southern New Mexico for the amount of work done shows up better than the Standard mine of this camp, and this is by no means the only mine that pay mineral rich enough to ship can be broken on. The gold bearing leads are not only remarkably rich for gold ore, but are also perfectly free milling. The average will run about \$40 from several fair samples of ore taken and the leads vary from one to four feet in width on several claims which have been partially developed. As an illustration of what the mines will do, we will state that including the dead work performed by the three owners of the Standard mine upon that property, they have realized \$20 per day for their labor, besides storing for future working about 100 tons of \$30 ore upon the dump, which will not pay to ship, but will be treated at the camp when works are erected there. R. M. Scott, after diligent search, has at last succeeded in striking a sufficient flow of water to commence the erection of a five-stamp mill, which with his associates he has purchased and will have ponding upon the ore of the camp in a very short time. The success of Gold Hill with reduction works in the camp will be assured. The mines have merit, notwithstanding the fact that mining men have deserted them. Within six months Gold Hill will be making large and regular shipments.—*Silver City Enterprise*.

MOSQUITOES, BEARS AND MINES.—J. A. Johnson, a well-known mining man, returned from Alaska a short time since. Mr. Johnson has been examining a mine on Douglas Island, supposed to be an extension of the Alaska mine, in the interest of some French capitalists. He brought with him ore specimens, which indicate the mineral wealth of that region. "Next to the rich ore," said Mr. Johnson, "what I struck the most forcibly was the mosquitoes. Why, sir, they kill the bears. Now it seems strange that a mosquito could kill a bear, but this is the way it is done: The bears come down from the hills into the marsh land to feed on roots and berries—a sort of cranberry found there. As soon as they get comfortably to work the mosquitoes attack them and go for their eyes. The bears get up on their hind legs to fight them off and sink into the swamp. The mosquitoes, which are of a most extraordinary size, keep at them until they are totally blind, and then they have them completely at their mercy. I have seen over a dozen bear carcasses in those swamps positively killed by the mosquitoes."

SHIPPING ORE TOO FAR.—Capt. Cooney was in the city this week. Having closed down upon some of his mines for the simple reason that the enormous cost of transportation to the works at Denver, Colorado, netted him nothing above expenses, the captain started in treating the tailings of the old mill. The parties with whom he contracted receive one-half, and furnish the requisite horse-power. The pulp ran through a 40-mesh screen, but owing to the heavy, silicious character of the quartz, carried some of the sulphurets and the fine gold down with it. A revolving 30-mesh screen remedied this defect, the fine tailings sticking to the belt. Capt. Cooney says he will never ship as far as Denver, and wants reduction works established in this city or in the Mogollons.—*Silver City Enterprise*.

THE May Lundy mine, at Mill Creek, Mono county, California, is said to have passed into the hands of a syndicate of English capitalists.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

MIDDLE BAR.—*Ledger*, May 29: W. A. Nevills, of the big tunnel, has determined to erect a Tustin mill at the mouth of the tunnel for the purpose of treating the rich ores of this district. It has been found by experience that the ordinary mill process is a complete failure in saving the gold contained in this rebellious ore. It is said, on good authority, that the tailings scattered along the gulch from the Mammoth mill to the river assay about \$10 per ton. From this it is evident that a different method of treatment is absolutely necessary. The Tustin mill works on the principle of Cornish rollers, and it is claimed by those acquainted with it that it is adapted to such ores as are met with at the Bar. After the rock is reduced to pulp, the whole of it will be roasted. To this end, Mr. Nevills has also determined to erect large sulphurets works near the tunnel, to have a capacity of treating five tons per day. A brick kiln is to be started near the Moore mine immediately for this work.

MISCELLANEOUS.—The New London, near Plymouth, continues to develop splendidly. The ledge is said to be from six to eight feet wide, and a portion of it containing considerable free gold. At the Kennedy the shaft has been deepened nearly 40 feet since sinking was commenced. They are also running a drift at the 600 foot level. The J. H. Hill gravel mine at Oletha has made a partial cleanup of \$1000. This mine has lain idle for a number of years on account of a lack of enterprise.

Mariposa.

COULTERVILLE.—*Gazette-Herald*, May 29: The Red Cloud mine is still grinding quartz, and report says they have a good mine and are doing well. The Bandercita mine is still operating about as usual. The last heard was that a shaft was being sunk from the lower level.

Nevada.

TO STOP DRIFTING.—*Nevada Co. Transcript*, May 27: We regret very much to learn from the office of the North Bloomfield and Milton Companies, in San Francisco, that orders have been given to the superintendents of both companies to stop all drifting work and discharge all their miners, in compliance with Judge Sawyer's recent decree, in the contempt case, wherein drifting was the only contempt committed. He so plainly stated that he would not allow any material from any mine or mining ground to be placed in any stream, under penalty of a fine of the value of all that might be taken out, that it seems impossible to continue mining in any way at present. The president of the North Bloomfield Company says that his company will, he thinks, try further experiments by the elevator process, in the hope that something may yet be done satisfactory to the judge. But as matters stand now, drifting is under the ban and a crime. Quartz may come next, and yet with these facts staring us in the face, our people send delegates to an irrigation convention and take no notice whatever of the eminent peril of our mining interests.

THE CROWN POINT MINE.—*Grass Valley Union*, May 26: The reported sale of the Crown Point, the Union learns, is upon the following terms: The intending purchaser, Mr. Nichols, has the privilege of working the mine one month, and crush the ore at such mills as he may choose, the profits for that time to go to the owner, Mr. Gauthier. If the result of the month's working is satisfactory to Mr. Nichols, he will then take the property at the price of \$300,000. A forfeit has been put up, but the amount is not stated.

MINE LEASED.—The Pennsylvania Consolidated has been leased to a company of eight working miners, who commenced operations on Monday by starting up the pumps to relieve the mine of water. There are two levels opened in the mine—one to the depth of 175 feet and the other at 275 feet. But little drifting has been done on the lower level. The first work that will be done will be to raise an air shaft between the two levels. The ledge in the mine is from six inches to two feet in thickness. The rock heretofore taken out has been of good quality, and specimen rock showing well in heavy gold and fine sulphurets has been produced. The mine only needs regular development to be a valuable property. The lessees are Chas. P. Whiting, W. A. Roland, H. H. Smith, Wm. Rumsey, Peter Cadden, Lee Hyatt, —Bastian, and one other whose name was not learned.

BADGER MINE.—The machinery of the Badger mine, driven by water-power, is working smoothly, and to all appearance the shaft, which is 180 feet in depth, will be pumped out and cleaned of any accumulation of debris in ten days. As far as exposed, the timbers of the shaft below the water line are in perfect condition.

QUARTZ FROM THE COE MINE.—*Grass Valley Union*, May 30: A cleanup of seven loads of quartz from the Coe mine (taken out by tributaries) was made at Frank Chesneau's little mill on Friday, which gave a yield of 10 ounces and \$6 of retorted gold, or an aggregate of \$171. This was equal to \$24.43 per load. The rock was not the best that is now coming out of the mine, as a crushing of a much better quality of quartz is now being made at Roger's mill, and it is believed will go \$50 per load. The above is the last crushing of quartz that will be made at Chesneau's mill for the present, as owing to the diversion of the Idaho water to the Crown Point and Badger mines, Wolf creek does not afford sufficient water to run his mill. Steam power will have to be applied to the mill, or some arrangements made to obtain water. The results of the custom work done at this mill are always of the most satisfactory character, as Mr. Chesneau is a very capable millman, having had many years experience in the business.

CREAK MINING.—*Tidings*, May 29: Allen W. Deadman, who has been for a long time on the police force in San Francisco, will soon start an extensive ground-sluicing business in the vicinity of his brother's ranch on Wolf creek, in the Cottage Hill district, 12 miles south of Grass Valley. The bed of the creek is known to be very rich in that vi-

cinity, and since Mr. Deadman had his hand hurt in the performance of his police duties, he has determined to try his fortune in mining. Several San Francisco gentlemen are interested with him. About 40 men will be employed in working the bed of the creek.

Placer.

IOWA HILL.—*Placer Co. Republican*, May 26: C. F. Hoffmann and Ross E. Brown, superintending engineers for the French syndicate, passed through town last week on their way to Damascus district to locate a position for the Burleigh drilling machinery, and to commence work on the big tunnel which is to open up their recent large purchases in that district. A large number of men will be employed, and Damascus and Indian springs will soon be lively camps. The Morning Star Company are running a 500-foot tunnel to work the rich ground they discovered some weeks since. J. B. Hobson has been awarded the contract and has employed George West, of Forest Hill, as foreman.

WASHINGTON.—The pumps have all been taken out of the Washington mine at Forest Hill, and work has been abandoned. Eleven men are working at the Live Oak. They have struck a body of gravel five feet thick, which prospects very well, and they are putting it in the dump pile.

Plumas.

GRANITE BASIN.—*Cor. Plumas National*, May 26: Mr. Johnson is running his mill on rock that would astonish the oldest miner on the coast for its richness. Mr. Graves is the busy man of the Basin. He is driving his tunnel on the Flower Pot, in good milling rock. Swan and Freethy are getting along well with their big contract of taking out quartz on the Siebert.

Shasta.

PLACER AND QUARTZ.—*Shasta Co. Democrat*, May 26: The Reid mill will soon commence crushing rock for Forbes & Co. Ollie Whitton is prospecting one of his mining claims on Squaw creek. An iron ore car is at the depot for the Golden Chariot mine, near Shasta. The Schaffer mine, situated on the east side of the river, opposite Middle creek, is panning out huge. Another rich pocket was struck last week. Within the past two weeks several fine gold quartz prospects were discovered on the west side of Squaw creek in Flat creek mining district. Blue gravel and cement diggings have lately been discovered between Reid's ferry and Quartz Hill. A streak six feet wide prospects ten cents to the pan. Frank Davis is sinking a shaft on the Clipper mine, on Squaw creek, and is taking out richer ore than ever. The vein is solid four feet in width. The P. M. Mining Co. of Squaw creek have ordered another Huntington quartz mill. The mill is on the way and will be running in 60 days. The Muchmore brothers are developing a fine mining property near Lower springs. The vein is six feet wide and is yielding very rich rock. During the winter months while water was plenty they run an arastra with good results. The boys intend to put up a stamp mill next fall. We stated last week that Tom Green's mill would be crushing ore soon. We have since learned that he is having trouble with the foundry where the machinery was purchased, which will delay the completion of the mill. The foundrymen failed to supply all the machinery according to contract.

UNCLE SAM MINE.—*Free Press*, May 29: Jack Conant returned from San Francisco last week, having ordered a ten-stamp quartz mill and a saw mill for the Uncle Sam mine on Squaw creek, owned by W. R. Conant, for whom Jack Conant is attorney. It is expected that these mills will be set up and ready for business by August 1st. The latest developments on the Uncle Sam are very flattering. A tunnel 230 feet long shows a ledge seven feet wide at a depth of 330 feet from the surface of the ground. The last assay shows \$602.71 in gold and \$9.48 in silver, giving a total of \$612.19 to the ton. As there is at least a thousand tons in sight, a stamp mill will be kept pretty busy from the start. Jack further informs us that the Matthews & Co. location, purchased from him some time since, is turning out well, their Huntington mill doing finely.

Sierra.

ALLEGHANY.—*Mountain Messenger*, May 22: Wm. Angove and others have leased the Rainbow ledge, at the old stope, and are developing there. The Buckeye Co., Alleghany, are breasting, and the gravel prospects well. T. H. Smith has two men employed taking out quartz from his ledge, very rich in gold. He has run in three tunnels on the ledge, and is clearing away a site for one of Forbes' mills down on the creek, above which he will put in a dam for the water-power. Specimen rock, glittering and ribboned with gold, has been extracted, and this mine is one of the most promising in Sierra.

Sliskiyou.

FORT JONES NOTES.—*Yreka Union*, May 26: Chas. Walker & Co. have recently made a rich strike in quartz on Indian creek, nearly opposite Geo. Baker's residence. Last Friday they pounded out \$20 from decomposed quartz. They have found a number of pieces ranging from \$5 to \$10. Some German boys from the lower country have found a ledge at the extreme head of New York gulch, which prospects well. The Crocker boys, on Deadwood, at the mouth of East Fork, are running their large arastra on good rock; they have a very favorable location to work. The ledge is large; one man can mine sufficient rock to keep the arastra running; as they have splendid water-power they can make good wages out of five-dollar quartz. Schroder & Werner's machinery is now on the way. A large force is engaged building the mill, boarding-house, etc. A number of teams are engaged in hauling the lumber. This is unquestionably the richest find that has ever been uncovered in Northern California. It will not be long until they will be molding and shipping gold bars the size of bricks. The hydraulic mines in this section are having a prosperous season. The Eastlick Bros., Wright & Fletcher, Campbell and others are literally making the dirt bowl. The new elevator, invented by the Eastlicks, is now being patented; and is a perfect success. It is the admiration of all the old miners, and reflects great credit upon these gentlemen, who perfected it under adverse criticisms and numerous obstacles that came in their way.

Trinity.

NEW QUARTZ DISCOVERY.—*Trinity Journal*, May 29: Mr. Jonathan Smith was in town this week and from him we have information concerning his recent quartz discovery on Indian Creek in this

county. The ledge is located about two miles above the town; when first discovered it was only an inch in width; he has sunk 14 feet and it is now from 8 to 10 inches wide. One ton was crushed in a hand arastra and yielded \$105. Two pieces of the rock which Mr. Smith kindly gave us as cabinet specimens show much free gold. Another ledge which he discovered in the same neighborhood also promises well, 1000 lbs yielding about \$20. There is a large scope of country lying between Indian Creek and Bullychoop which should receive attention from quartz prospectors.

NEVADA.

Washoe District.

HALE AND NORCROSS.—*Virginia Enterprise*, May 24: The drift south from the bottom of the deep winze on the 3200 level is now 67 feet in length, running in a due southerly direction toward the Combination shaft, which has reached that level. The drift is skirting along the east wall of the ore vein, and no crosscutting will be done before the connection is made. Owing to the necessary drainage grade a little downward toward the shaft, and the having to pass the debris excavated backward through the drift, upward through the winze and out through the 3100 level, the progress in this drift is necessarily slower than it would otherwise be. This, however, will be changed very materially when a connection is made at the other end, from the Combination shaft. On the 2900 level, the north and west workings toward Savage south line show no improvement from last week. Streaks and bunches of fine ore continue to be met with, but they do not concentrate as yet into the expected and long-looked-for bonanza. The prospects, however, are exceedingly favorable at that point, as well as in the explorations above the 3100 level.

CHOLLAR.—Rattling good progress, so to speak, has been made in sinking the Combination shaft, about 24 feet per week being the rate, and to-day the 3200 level is reached. This has been the objective point, making it the deepest vertical mining shaft in the known world. It will be continued 60 feet deeper for a sump or well for the big pumps, and further sinking discontinued until the present lowest levels are satisfactorily explored. No increase of water is met with in this deeper sinking, although the bottom of the shaft is now in the main Comstock ore channel, having passed through the east or hanging wall on the regular dip or inclination of the lode to the east. A large amount of quartz is met with, showing more and stronger mineralization, and it is by no means impossible to run into good ore before the bottom of the sump is reached.

GOULD AND CURRY.—On the 600 level the upraise at the south line, next the Savage, has been extended 38 feet, making a total upwardness above the track floor of the 600 level of 141 feet. It still continues in a strongly mineralized quartz formation, which bids fair to develop good pay ore before the 400 level is reached. The east and west crosscuts from this upraise show no material difference from last week, being in quartz giving low assays.

CON. CALIFORNIA AND VIRGINIA.—About 420 tons is now the regular daily yield, giving an average assay from the mill battery samples of about \$14 per ton. Reopening the old stopes penetrated by the southwest drift on the 1400 level progresses favorably, and on the 1600 level west crosscut No. 2 has connected with the old north drift, giving good air circulation and other material advantages.

ALTA.—About 50 feet still remain to drift in order to connect with the old Lady Washington workings on the 700 level. Until the connection is made no crosscutting will be done into the ore vein, which lies to the west. A connection for a good air circulation is the main object at present.

BEST AND BELCHER.—The reduction of the water in the bottom of the Osobiston shaft progresses slowly, by reason of the great area of ground to be drained. The water is being steadily reduced, however, and will be all out in due time.

SAVAGE.—The main lateral drift south on the 600 level from the Gould & Curry was extended 46 feet, making a total length of 116 feet, driving directly for connection with the main shaft of the mine. It continues in strongly mineralized quartz, vein porphyry and clay.

POTOSI.—Some delay was met with in the diamond drill arrangements on the 3100 level, and trouble from the broken, seamy, clayey formation met with, consequently there is nothing new or favorable to report this week.

MONTE CRISTO.—All work still concentrated in advancing the drift west on the 150 level from the new shaft. The rock seems to be getting a little softer, indicating near approach to the ore vein.

OPHIR.—On the 700 level the main exploration drifts north and south are making usual progress, both running in favorable looking vein matter—porphyry, clay and quartz.

SIERRA NEVADA.—On the 520 level, west crosscut No. 2 was extended 36 feet in the same hard quartzite and porphyry formation, with a little seepage of water. Total length, 577 feet.

YELLOW JACKET.—Daily yield, 140 tons, keeping the Brunswick mill steadily supplied. The old workings above the 1300 level continue looking and yielding well.

CROWN POINT AND BELCHER.—Daily yield 375 tons from the old workings, all the way from the 1700 level upward. No new feature of interest to report.

KENTUCK.—About 60 tons of ore per day continue to be yielded from the old upper workings—all low-grade ore.

Bernice District.

LOVELOCK.—*Cor. Silver State*, May 29: The Bernice mill has been running steadily on ores from various mines in that district for a week past, and has produced about \$12,000 in bullion. G. W. Bothwell, owner and manager of the mill, is building a residence and store at Bernice, and seems to be fully satisfied that the camp will be prosperous and permanent. About a carload of merchandise is now at the depot at this place, awaiting the completion of the new store, which will be opened shortly and be a great convenience to the miners. Our mines seem to be taking a new start all around. The nickel mines, which were under a cloud for awhile, have paid up the hands, and will shortly resume operations. Uncle George Lovelock returned from the city last week to start things going.

Central District.

LOCOMOTIVE.—*Eureka Sentinel*, May 28: The Locomotive mine, in Central district, Humboldt county, owned by J. F. Clark, is said to yield ore milling 322 ounces in silver per ton. The ore is refractory and is shipped to Salt Lake for reduction.

Columbus District.

HOLMES.—*Candelaria True Fissure*, May 29: In the eastern end of the eighth level we are extending the level east. It is in good-looking ground, with a small streak of good ore in the face of the drift. Over the point where we made the connection between the eighth and top of ninth raise, we have a good stope of ore. The ore is high grade, and the stope is producing well. In the raise 100 feet west of the ninth raise we have discontinued crosscutting for the present. Opposite the ninth raise, ninth level, we are crosscutting toward the hanging wall. In the crosscut we struck a small streak of good ore. This ground looks exceedingly favorable. We have good prospects in East Thomas. When this connection is made it will ventilate the whole eastern portion of the mine. The stope 60 feet east of last turntable, first shaft level, looks exceedingly well. This has been a splendid stope. It has produced well ever since a year ago last November, and looks just as well now as it ever has. The stope 50 feet below the first shaft level, and directly under the last-mentioned ore body, is still producing well. At point six we are getting some good ore. In the intermediate level between the first and second shaft levels we have a good prospect, from which we are extracting some ore. Sixty feet west of Cross development we are getting some good ore. The Creer stope has improved since last report. The intermediate stope between the fourth and fifth levels is giving considerable \$60 ore. A small amount of ore of fair grade is being taken from the west drift on the fourth level. The intermediate stope between the third and fourth levels, east of the shaft, is giving some \$60 from a bunch that looks promising. The stopes above the west drift on the third level are giving a little ore of fair grade. The east stope on the second level is looking much the same and is turning out considerable \$60 ore. The intermediate stopes between the first and second levels are yielding the usual amount of ore. Bullion shipment, May 26th, \$10,168.63.

Ellsworth District.

QUIET.—*Belmont Courier*, May 22: Ellsworth is very quiet. No mining enterprise of any kind is being conducted there.

Esmeralda District.

AURORA'S PROSPECTS.—*Virginia Enterprise*, May 27: Colonel A. C. May, writing to a Comstock friend, says: Aurora, Esmeralda county, has a bright future. "The new English company, 'The Consolidated Esmeralda, limited,' is pushing work in a comprehensive manner. Its central point of operation is ex-Governor Bladell's old pet mine, the Humboldt West, where a shaft has been sunk more than 300 feet and four levels run. Sinking is still being prosecuted diligently. At present depth the vein is upward of 45 feet in width, the ore being of good grade, mostly gold-bearing. About 80 men are employed. There are steam hoisting works and everything complete to prospect the mine to a depth of 1200 feet. The mill at Del Monte is kept running steadily, and yields enough to pay all expenses, so that stockholders in the old country are not being cinched for assessments. It is the intention to build a 50-stamp mill at the mine and 100-stamps on Walker river. There is sufficient ore in sight now to keep the two contemplated mills and the Del Monte mill closely at work for ten years, and pay handsome dividends. Our British brethren who have invested their money in Nevada mines feel much elated over the prospect, for Aurora's outlook is certainly bright. She sent out upward of \$14,000,000 in bullion inside of four years, and it is not a fair supposition that the surface scratchers got it all.

THE DICTATOR.—*Walker Lake Bulletin*, May 27: The Dictator shaft is now down 100 feet, at which depth the ledge is from 15 to 20 feet wide. A cross-cut will be started immediately to ascertain the exact dimensions, when drifts will be run each way on the ledge. Quite a number of prominent mining men visited the mine a few days ago, among them being Gov. Kinkead, H. M. Yerrington, R. P. Keating, Dr. Bronson and Robt. Pixley, all of whom expressed themselves as being very highly pleased with present developments and the prospects for a rich and permanent mine. Supt. Keating, of the Hale & Norcross, took quite a number of samples and had them assayed. One went over \$800 in gold, another, \$487 in gold and \$5 in silver, and the average at the bottom of the shaft, \$75.35 in gold, being on top of the ledge on an incline. Should the cross-cut show up in proportion, it will prove the largest mine in this part of the country.

Jefferson District.

GOOD ORE.—*Belmont Courier*, May 22: The Jefferson chlorides are taking out good ore.

Pennsylvania District.

MORE STAMPS.—*Pioche Record*, May 22: During the week 4500 ounces of bullion was brought from Pennsylvania district by G. R. Barton. They will place five additional stamps in the mill as soon as possible. At present the crushing capacity at the mill is but six tons daily.

San Antonio District.

CHLORIDING.—*Belmont Courier*, May 22: It is thought that some chloriding will be done in the mines of San Antonio soon.

Reveille Creek District.

THE OHIO.—*Silver State*, May 26: Yesterday J. J. O'Toole, N. Treweek and J. M. Porter, of Salt Lake City, and Prof. Foster, of Colorado, returned from the Ohio mine at Rebel creek, whither they went last week to examine the property. Mr. Treweek, who is an experienced mining man, informed a *Silver State* reporter that he considers the mine a very fine property. The mine is opened by a tunnel to a depth of nearly 400 feet by actual survey on the dip of the vein, and it can be worked by tunnel 400 feet deeper. The ledge is from two to 40 feet wide, and there is now some 15,000 tons of ore on the dump, and at least three times as much in sight in the drifts. The ore averages 42 ounces of silver and \$7 in gold to the ton. It is almost wholly free from base metal, and can be worked to a high percentage of its assay value by the ordinary wet process. The owners will probably build a

mill on the mine in the near future, though they have not yet determined upon the time, or the capacity of the mill. Much of the ore has been shipped to Salt Lake, but as the expense of hauling it by teams to this place and shipping it hence by rail is necessarily great, only the highest grade of ore will bear it.

ARIZONA.

CHLORIDERS DOING WELL.—Cor. Prescott *Courier*, May 28: Nothing much of any note to chronicle this week from Turkey creek. McLain made a shipment of ore last week and a rich strike in the Longfellow mine this week. So we may class him among the lucky ones. The ore shipped by Randolph & Ryan netted them over \$600 per ton. They will make another shipment next week. Roach is delving away on the June Bug, which is looking fine.

PECK.—Harry Norton, who has leased the Silver Prince, is doing very well. He is drifting on high grade ore and is well pleased with the prospect. "Blanco" White made a rich find last week in Crazy Basin, two miles east of the Peck claim. The ore is rich in horn silver. Major McKenney made a rich strike in one of his mines in the Peck district. The McKinnor Bros. have a fine showing in the War Eagle. The ore body is large and of very good grade. They have a very fine lot of high grade ore on the dump. Tom Goodwin will start his arastra, in a few days, on ore from his mine in Bradshaw Basin. The claim is a recent discovery. He has five tons of rich gold ore to start on.

WALNUT GROVE.—John Mahoney has been running the Callen mill, with good success, on ore from his gold mines, Constellation and Rose. A very rich strike was made last week in the Rose south of the old working shaft. The ore strata is 15 inches wide, and will mill fifty dollars per ton. Years ago, old experienced miners predicted that the Rose would at some future time be classed among the best paying gold mines in the county. Present developments would seem to verify the prediction. Morrow & Robbins are arastrating on a claim bearing their name, and are doing very well. The mine is situated near the old Hæcher mill-site, and is a very good prospect. Taking all in all, the mining outlook was never brighter in Yavapai county. True, there are very few big companies operating; but there are men who have made success a certainty, where big companies have made a failure. The chloriders are busy at work in the different camps of the county, and where the chloriders are developing the outlook is always bright.

COLORADO.

LITTLE ALICE.—Georgetown *Courier*, May 29: Mr. Slater, superintendent of the Little Alice Mining Company, whose property is situated on Fall river, contemplates soon commencing active operations in the way of sluicing on the placer claims of the company. The company will probably put up a stamp mill this season, when the property will be more thoroughly explored. An enterprise in the shape of a tunnel is now under way at the base of Griffith mountain. It is started to explore the Nancy Smith and other lodes. A fine vein of high-grade ore has been exposed in the Richmond lode, Saxon mountain. Clark & Co., lessees on the Wolverine lode, are sinking from the adit level, and at 40 feet have two inches of solid ore, carrying particles of native silver. It is reported that a sale of the Little Giant lode, on Red Elephant mountain, is in contemplation. Several leases on the Mendota are showing up splendidly. Morrell & Co., who are leasing on the Victoria tunnel, level west, have opened up ground for 250 feet, and during the whole of this distance heavy lead ore is exposed from six inches to two feet in thickness. They will make another shipment of 35 tons next week. Peterson & Co., lessees on the upper workings, are operating upon a large and continuous body of galena, and expect to output at least 30 tons this month. It is stated that Joe Podvin, who is working the Muldoon lode, on McClellan mountain, has opened a vein of ore four inches in thickness, which, according to a test recently made, returned 600 ounces silver per ton. Work will soon be commenced on the R. E. Lee lode, at the head of Beaver Creek. Both the shaft and adit show a large vein of mineralized quartz. In early days some good ore was taken from these workings. Ten men are at present engaged on the Two Sisters mine, and we understand that the company owning the property will work it very extensively in the future. It promises to be one of the leading mines of Silver creek ere long.

IDAHO.

THE SMELTERS WILL START UP.—Ketchum *Keystone*, May 22: Supt. J. H. Hardess, of the P. M. & S. Co., returned home from Omaha yesterday, having left Messrs. Wright and Borie, of his company, at Granger, en route to San Francisco. We understand that Mr. Hardess comes with the gratifying news that the works at this place will be blown in for a summer's run in one week. We understand this is owing to the consummation of suitable arrangements at Omaha, whereby the P. M. & S. Co. can afford to pay competing prices for the ores of the district. This will be a welcome word to the miners of this section and the best of news for the citizens of Ketchum. There is no truth in the report that the smelters were sold to the Omaha Works. They have sufficient ore, flux and fuel on hand for a considerable run, and will start up with the determination to compete for a continuous supply from the mines of Wood River.

THE NYE PUMP ENTERPRISE.—Coeur D'Alene *Record*, May 28: The big gravel pump on the Nugget Fraction claim will soon be working to its full est capacity. The sluice-boxes, elevated about ten feet above the ground in order to give sufficient fall for washing and abundant room for dumping purposes, are nearly all in place and will soon be in use. The gravel prospects well 25 feet below the surface, indicating that there must be at least 15 feet of "pay dirt." The fuel is reported poor, too poor for the two boilers now set up to furnish sufficient power. With first-class fuel they would be equal to 100-horse power. Larger ones are expected in a few days, and when they arrive that difficulty will vanish. Supt. Cargill says "the enterprise has been thoroughly tested in other places. It is no experiment. The company know what they are doing."

WESP GULCH.—Late Tuesday afternoon the reporter rode up the Littlefield road to Wesp Gulch to ascertain what is being done there by John Comerlihl, who, about six weeks ago, bought claim No. 1 from Lorenzo Aramburo, and a few days later began putting in a bedrock flume. A little more than a year ago there were as many as 16 different owners in the claim. It changed hands several times, Nathaniel Vestal being at one time a partner. He and others sold out to several Georgians, who began work about 200 feet up the gulch from the road by sinking a shaft and running a drain. They sunk the shaft only 17 feet and did not reach bedrock, but they found gold enough in the gravel to encourage them to go below and run a tunnel up what they believed to be the deep channel of the gulch. They began on the Butte claim and ran a tunnel and drain-race up under the road and a short distance up the gulch, but not far enough to test its value. They sunk four shafts, one just below the road, striking bedrock at a depth of 22 feet. Mr. Comerlihl began work five weeks ago, and first built a reservoir across the gulch about 500 feet from its mouth. He then began putting in his bedrock flume, which is completed a distance of 225 feet, and is believed to be within 25 feet of bedrock. The upper boxes are about 14 feet below the surface. The gravel prospects fairly, and there is good reason to believe that the bedrock flume enterprise will be a paying one. The gulch is nearly as large as Alder, but not so wide, and hence does not include so much placer ground. It will average about 60 feet wide for a distance of one-fifth of a mile. Above that it is much narrower. One hundred and fifty feet above the reservoir is the California ditch. On a bar just above the ditch fair pay has been obtained with a rocker for several months past. Wesp gulch cuts the old wash squarely, and over in Cougar gulch, which heads between Wesp and Gold Run, the old wash is quite unbroken and is very similar to that shown up by the operations on the Badger claim, near the head of Nugget gulch between Alder and Buckskin. From his reservoir Mr. Comerlihl has built a 10-inch flume 250 feet along the hillside, giving him 70 feet fall for his hydraulic. The gulch supplies plenty of water to work three months of the year without using the reservoir. By the aid of that the season of work may be considerably prolonged. Three men are now employed.

SILVER MOUNTAIN.—Idaho *Statesman*, May 27: Patsy Marley came in from Silver Mountain day before yesterday. He left here about the 20th of April and stopped several days in Idaho City and two days in Banner. The distance from Banner he calls 18 miles. Mat Graham's company got out of provisions and powder, and had to go to Atlanta and pack it in on their backs. Mat is there and makes a hand. Four other men are there at work and have been all winter, and worked two shifts, night and day, in their tunnel. They have run 200 feet in the hardest kind of rock, and have 40 more to run before striking the lead, and will then be 200 feet from the surface. Will Austin and Wm. Irwin own the Snowbird, about two miles from Graham's lead. The Snowbird and Big Croppings join together, or rather is the same lead. The latter is owned by Patsy Marley. Irwin sent a man out with Austin about six weeks ago, and they are at work running a tunnel across the lead. They are in 30 feet and will have to run 50 feet more to cross the lead and strike the best paying streak. The rock they have run through will pay about \$50 per ton on an average. Marley's lead will be very well developed by the completion of the Austin and Irwin tunnel. It will be the 15th of June before pack animals can reach the camp.

MONTANA.

RESUMPTION OF OPERATIONS.—*Inter Mountain*, May 25: The Cora mine, owned by Roudeshush & Young, is 115 feet deep. The lower level exposes a well-defined and regular vein of silver-copper ore from five to 12 feet wide, much of it being good smelting ore, and some of it requiring concentration. It is an old and well-known property, and is regarded as one of the coming mines of the camp. It has not been actively and continuously worked since about 1833, and the resumption of permanent operations will be watched with considerable interest. The shaft will be at once sunk to the 315-foot level. Another property which has been idle for some time is the Grey Rock, owned by Judge Davis, and which in years past has produced, from a very extensive vein, thousands of tons of fine milling ore from above the water line. Three years ago a three-compartment shaft was sunk by John Downs at a point some distance south of the outcrop, and from the bottom, at a depth of 300 feet, cross-cuts were extended north. The ore was base, having turned chiefly into copper pyrites, and work was not prolonged. Copper mines are valuable now, however, and it has been determined to resume development. The main shaft will be at once dropped to the 400-foot station, and explorations from that point will be active and continuous. The Grey Rock is supposed to be an extension either of the Bell or High Ore lode, and is justly regarded as one of the most extensive properties of the district.

THE PYRENEES.—*Inter Mountain*, May 28th: From Mr. J. Ross Clark, who returned a day or two ago from a trip to the Pyrenees mine near Cable, it is learned that satisfactory progress is being made in developing the property, and that the output is fully up to their expectations. Mr. Cameron, the principal owner formerly, had tapped the vein by a tunnel at a depth of a little over 100 feet. At this depth he had run levels both ways, opening the pay chute for a distance of about 800 feet along the vein. The ore body is from three to seven feet wide. He had staked out the most of the best ore above this level and worked it in a five-stamp mill. The company is now sinking a shaft so as to open the vein almost beneath the point where Cameron tapped it and at a total depth of 200 feet. Some 60 or 70 feet of the sinking is already done, and they are getting down at the rate of a set of timbers—five feet—every 36 hours. Thus it will take them till about the middle of July to complete the shaft. From its bottom the vein will be crosscut and levels run in a manner similar to those in the workings above. If the body of pay ore is as extensive below as it is in Cameron's levels the company will have one of the finest gold properties in the Northwest. While the work is being done the company will continue to take out ore from the 100-foot level and work it in their new 10-stamp mill, which has now been in

operation for about 30 days. Cameron's old five-stamp mill was entirely displaced, and the only part of the machinery which the company is using is the engine and boiler. They are not picking the ore as Cameron did, but are putting everything through the mill with an average saving of about \$10 per ton. The average of the pay chute is, however, much above this figure, but they are treating a good deal of ore which Cameron had for the time being laid aside on account of its low grade. No cleanup has as yet been made from the new mill. Five vanners, four in number, are now being added to the plant, and the accumulated tailings of several years past from Cameron's mill—there being several hundred tons—will be worked over. Assays show that these tailings still contain \$20 per ton in gold.

NEW MEXICO.

BESY.—Silver City *Enterprise*, May 28: There are a number of miners busy at Lone Mountain and ore is being produced regularly. It is said that Geo. O. Smith contemplates the erection of a smelter at Georgetown. Capt. Stewart, who shipped a carload of ore from the Peartless to the Denning sampler last week, was greatly dissatisfied with the result. He will ship to Socorro in the future. Active work has been done upon the lead properties near Central City, by Hutchinson and Walker. Five carloads of ore have been shipped so far this month, and as much more is now on the dumps. It ranges in value from 6 to 20 ounces in silver and from 40 to 60 per cent in lead. A private letter from John A. Miller, received Tuesday last, says: "My last shipment of 12 tons went at the rate of 230 ounces in silver, one ounce in gold and 30 per cent in copper." Three men are at work upon the Sally, a new strike of considerable importance recently made in the Burro mountains. The ore is silver glance, some of which is very rich. J. B. Malone, who has a lease on the Tenderfoot mine at Malone, is now taking out on an average one carload of ore per month, which nets him about \$1000. Mr. Malone is working but four men, and does not ship anything under 60-ounce rock. A representative of the *Enterprise*, accompanied by E. H. Kinney, superintendent of Emma and Hidden Treasure mines, went through those mines yesterday, and was surprised to find so large a quantity of ore in the different workings. These mines are owned by J. H. Flagler and other New York capitalists, who have turned their interests over to the gentleman above named to operate as his judgment dictates. Since he ordered work commenced upon them about one month ago the force has been increased until it numbers 27 men, and the pay ore exposures are innumerable. The claims adjoin the famous Brennen '76 mine, which is noted as the greatest producing mine in southern New Mexico, and the mineral is found in the same character of quartz and slate in line; some of the ore chambers being remarkably rich and large. Mr. Kinney, after many experiment tests of the decomposed lime found near the ore chutes, finds that it assays about \$20 per ton. This ore has heretofore been cast aside as waste, but hereafter it will be carefully stored away for treatment at the company's mill.

OREGON.

PINE CREEK.—Cor. *Bedrock Democrat*, May 24: Cornucopia is experiencing a slight boom at present; building is going on at a brisk rate. Snow has almost entirely disappeared, so that the prospector can wend his way out over the hills in search of the precious metal. Within the last few days there have been some good locations made on what is called the Simmonds mountain. The Simmonds mine is now being worked; a force of ten men is employed. The ledge is very rich in galena ore. The Whitman mine is now down 160 feet. A large size winze has just been placed in position. The extension of the Whitman, the Alta, is to be sunk 250 feet, the contract being let out to Messrs. Lindgreen and O'Malley. James Maloney's ledge, the O. R. & N., has been in dispute in the Justice's Court, other parties laying claim to the same. It is undoubtedly a rich ledge; 14 ounces of gold were recently pounded out in a hand mortar. The Dominion, Burdette & Co., is now tunneled to a depth of 140 feet, a contract having been let to H. Kern & Co. to tunnel 150 feet deeper. The ledge assays very rich in silver. A two-stamp quartz mill has been put in operation by Portland parties. If the enterprise succeeds the company will soon put in a large mill. The O. G. M. Co. have put men to work clearing off a mill site, one-fourth mile above town. A saw-mill will also be erected on the same by the company.

PLACER AND QUARTZ.—Jacksonville *Times*, May 28: Considerable work is going on in the Goddard Hill district. Prospecting continues in many places, and some excellent discoveries are reported. D. King & Co. have struck excellent drifting diggings on Jackson creek, which are said to pay \$4 per hand daily. The McDford Reduction Works are making a run on ore from the New Discovery mine, which promises well. Bedrock was struck in the Sterling mine a short time since, and everything is progressing satisfactorily there. L. D. Brown has put a quartz mill in the vicinity of Swinden & Co.'s ledge in Rock Point precinct, which will soon be running in good style. Jas. Herd's quartz mill has been moved to the head of Jackson creek, where it is engaged in crushing cement for Blalock, Owings & Co., with excellent results. S. McConnell has sold his placer diggings on Wagner creek to Capt. Thos. Smith and Geo. H. Lynch for \$1100. The purchasers secured a bargain in our estimation. The Hydraulic mines of Jackson and Josephine counties are still running, and have enough water for present purposes, though the supply will commence to fail before long. Messrs. Klippel, Howard and Keaton are engaged in cutting a ditch of considerable length to their mines on Applegate, from which they expect excellent returns in the future. Sampson McConnell has been doing very well at his placer diggings on Wagner creek. He found a fine nugget of gold worth \$281 a few days since, and has taken out several hundred dollars worth of coarse gold besides this season. The quartz mill on Wagner creek will soon be in running order. It is a large and first-class one and is expected to work wonders in that mining camp.

Ione District.

GOOD ORE.—Belmont *Courier*, May 22: From John H. Becker we learn that a very fine streak of ore has been struck in the Indianapolis mine, near Ione. This mine is being worked under the direc-

tion of R. C. Langworthy, and has in the days gone by produced large quantities of high-grade ore. It is now being thoroughly prospected and opened, and as soon as the developments warrant, reduction works will be erected for the treatment of the ores.

Ophir District.

MEN ENOUGH.—Belmont *Courier*, May 22: The Chicago Mining and Reduction Company are employing about all the men that can be conveniently worked at present. We would advise miners not to rush in there too fast, as there is not work for every one that comes along. The capacity of the mill is being increased and other improvements made. Ophir is a live and prosperous camp, but it is not large enough to supply work for all the unemployed in the State of Nevada.

Reveille District.

GLA MILL.—Belmont *Courier*, May 22: The Gila mill, at Reveille, will soon drop stamps on ore from the company's mine. Reveille will be a lively little camp this summer.

Spanish Belt District.

BARCELONA.—Belmont *Courier*, May 22: Mike Hearon returned from Spanish Belt on Sunday. He has a very high opinion of the Barcelona mine, and is satisfied that as soon as it is properly worked it will prove one of the most productive properties in the State. The Belt, he says, has never been properly prospected for the rich mineral deposits that are there hidden, awaiting enterprise to discover and develop them.

Union District.

EXAMINING MINES.—Belmont *Courier*, May 22: Some San Francisco mining experts visited Union district last week to examine the mines owned by George W. Veach, Frank Bradley and others. The mines of Union district will give employment to thousands of men when they are properly handled.

Washington District.

AT WORK.—Belmont *Courier*, May 22: Shaw is still working his mine in Washington district. The ores in this mine are of a smelting character. Capital will handle this mine some day and then there will be a big stir in that section.

WAITING FOR SILVER TO GO UP.—The owners of the St. Helena mine, Washington district, are waiting for silver to touch par before they commence operations on that property.

UTAH.

SANDSTONE NOTES.—*Southern Utah Times*, May 23: At the California, a new drift has been started on the 700 level, north. A fine body of ore has been struck, the extent of which cannot yet be ascertained. The Silver Gate continues to show up in good shape. Drift is now in about 40 feet, showing four feet of splendid ore assaying 1028 ounces in silver. Bales & Holling are now sending a 50-ton lot of ore from the Gate to the Leaching works. In the Buckeye, the south drift on the 700 level still produces ore. In a crosscut on the same level, running in a northerly direction, several nice stringers of ore have been met with throughout its length of 50 feet. These stringers evidently run to the main ledge, which will probably be tapped within 20 feet and a good body of ore opened up. Work progresses favorably at the Stormont, which continues to furnish a regular supply of ore to the River mill. A few days ago, F. W. Taylor, a member of the Russell Process Co., came up from New Mexico. His visit was for the purpose of examining the working of their process in the Harding works. After a brief stay in camp he proceeded to Pioche to inspect the Godbe works. The Harding works have been operating successfully since the enlargement of their plant. The rolls are in place and it is expected that crushing will be begun about Wednesday next. The supply of crude ore will be sufficient to keep the rolls running for a long time without drawing upon the tailings dump.

ALTA COMPANIES.—Cor. Salt Lake *Tribune*, May 20: According to the invitation extended to your correspondent per Messrs. David Hepburn, Wm. Green and Wm. Weir, the lessees of the Old Emma works, I visited the mine and find a vast amount of work has been performed in that celebrated mine. We started from the mouth of the Bay City tunnel about 1600 feet in a northerly direction, then we turned east about 350 feet, at the end of which we ascended an incline shaft 180 feet, making a connection with a small tunnel about 50 feet long leading to the ore body, or where the cave happened years since. The lessees have been working on the same ore body all last year, in removing and washing the same, and have done well. They have still their lease on the same and have been working all last winter removing ore through the Bay City tunnel. Now they have a large body of ore on the dump ready for the washing process. They have already nearly 300 sacks of ore ready for shipment. Each sack averages 110 pounds and \$140 per ton. An extra force of men have been employed at the New Emma for the purpose of putting up the stacks, and Mr. John Ford will start the machinery to-morrow for the purpose of pumping the water out of the mine. Superintendent James Tavish, of the Moltke mine, is here. He has been to the mine and has everything ready to start as soon as he receives orders from Henry Wagner, Esq., the owner. Tavish expects to make a larger shipment this year from the Moltke. A good quantity of ore is ready for shipment in the Kittie mine, the property of Charles Tavish and James Tavish. Mr. Albert Fuge, the engineer-in-chief and foreman of the Frederick, told your correspondent he has everything ready to start as soon as he receives his supply of coal. Foreman Siceman was in town yesterday and reported that the east drift of the Superior tunnel is looking well and his men are in good spirits.

THE CRESCENT.—During the past week the Crescent Company shipped 22 tons of high-grade ore. The shipments of concentrates for the past four days aggregated 125 tons. The first big shipment of Crescent concentrates was made the first of the week. Four hundred tons were in the lot; the assays went about 25 ounces silver and 35 per cent lead to the ton, and about \$10,000 was realized by the sale of the concentrates. The Daly bullion shipment for the week aggregated eight bars of silver.

ORE SHIPMENTS.—The Mackintosh sampler received from the 22d to the 28th inst., inclusive, 227,840 pounds of Daly and 19,400 pounds of Sampson ore.

MECHANICAL PROGRESS.

Cast Steel for Crank Shafts.

In a paper recently read before the British Steel Institute by Mr. Hall, he again deals with the vexed question of marine shafting and cranks. He reminds the members that the paper which he read two years ago on "Cast Steel as a Material for Crank Shafts," and which related entirely to material, was freely criticised. Mr. Hall, however, states that up to the present time he has seen no just cause to alter, in the slightest degree, his opinions as set forth at that time. On the contrary, his then convictions have been intensified beyond all expectations; and if he dared enumerate the number and condition of broken shafts that had, since that date, been brought under his notice, he should considerably astonish steelmasters.

Cause of the Failure of Steamer Shafts.

Mr. Hall, in an elaborate and able paper, proceeded to show that shafts rarely broke through pure overwork, but through the shaft revolving when bent or sprung into an irregular line of bearing. And he described the success which is attending the patents which Jessops are now manufacturing, having for their object the prevention of accidents to shafts, such as Turton's patent built-up crank shaft, and Verity's patent flexible ball coupling.

Flexible Crank Shafts at Work.

Mr. Hall recommends flexible crank and propeller shafting. He gives several instances of the satisfactory working of Verity's coupling. A ball coupling purposely thrown a quarter inch out of line has been at work for over two years and is still working well. Since Christmas there has also been a flexible crank shaft, 10-inch diameter, working in a steamer that had previously given great trouble with her crank shafting, but which is now giving every satisfaction. We gather the above from the English correspondence of the *Iron Age*.

NEW PROCESS OF MANUFACTURING CAR WHEELS.—At the works of the Dickson Manufacturing Company, in Wilkesbarre, a new machine and process, patented by J. J. Carr, has been tested with satisfactory results. It is claimed that while on the old method of molding, casting, dressing, and boring the wheels the average product of three men per day of 12 hours is 18 wheels, with the new process the same number of men can turn out one perfect wheel every minute, or 720 wheels per day. The principal feature seems to be the substitution of a steel core for one of sand in casting the wheel. This has been tried before, but no one had hit upon a means of getting this core out of the wheel after it was cast. This is now accomplished by a center key, which falls out upon a single stroke of the hammer and lets the steel core drop out, leaving the hole in the wheel perfectly true, and ready to be put upon the axle without any dressing or boring. The sand is run into the molding boxes by a hopper, and both matrices are molded and the pattern drawn out by the single revolution of a shaft driven by steam power. The matrices are borne away upon movable platforms to the cupola, and then the piece is cast as under the old process. The molding is done as rapidly as a revolving disk can carry the boxes under the pressers.

PITTSBURGH TEACHING ENGLAND TO MAKE STEEL.—It may read a little strange, but it is nevertheless a fact, that a prominent English iron manufacturer should send his son to America to learn how to make steel. Mr. Edgar Richards, the eldest son of E. W. Richards, an iron manufacturer of Middlesbrough, is, or a short time since was, at the Edgar Thompson Steel Works, actively engaged in learning the business of steel-making on American principles. This enterprise was entered upon in consequence of the fact that many Englishmen interested in the iron business have returned from short visits to this country with many "wrinkles" in the art, which are esteemed of much value in England. Among such visitors are named Mr. William Moore, of Messrs. Jennings & Co., of Middlesbrough; Mr. Theodore Fox, of the Newport Rolling Mills, in the same town; Mr. Thomas Wrightson, of the Teesdale Iron Works, Stockton; and Mr. Edward Williams, of the Linthorpe Iron Works, Middlesbrough. All these parties are men of experience in iron manufacture and all agree in swelling the volume of praise which is ever heard when an Englishman, who knows something of iron and steel making, and has watched the style of doing it in the States, gives his friends the benefit of the views which their transatlantic journey has developed. So says a reliable correspondent of an American journal.

COMPARATIVE ECONOMY OF EXHAUST AND DRY STEAM.—Supt. Manning, of the Amoskeag Company, Manchester, N. H., says, in a note relating to the comparative economy of exhaust and dry steam for heating: "On our lower level, where we always use a large amount of steam for dyeing and drying in case of low water, I can run out 36-inch by 6-foot Corliss up to a thousand horse-power without any change in the boiler except a slight increase of pressure, and whatever increase of fuel there is (of course there must be some) is so small that it falls within the daily variation due to other causes."

Steel Half the Cost of Iron.

Sir Nathaniel Barnaby, of the British Admiralty, says the English correspondent of the *American Manufacturers' Journal*, remarks that years ago the navy constructors had to pay an exceedingly high price for iron—a price heightened by the severe tests to which the material had to be put. The great change which has now come over prices can be seen from the fact that the material at present used—mild steel—is only half the price of the iron formerly employed. This, however, is cold comfort for basic steel-makers, or the makers of dephosphorized metal. Mr. B. Martell has found the basic material as used in shipbuilding in Germany to be very unsuitable, and he asserts that the German steelmasters admitted to him that it was unreliable. The fact, too, that Lloyds still decline to accept for classification vessels built of basic steel is a serious matter to the Thomas-Gilchrist steelmasters. Lord Ravensworth, however, and other engineers express the hope that Lloyds will before long see their way to modify the standard for the basic metal. It will well bear a test of from 24 to 27 tons, while Lloyds are requiring from 28 to 32 tons.

It is feared, however, that the general rage for cheapness in these days of economizing will lead to trouble, if more care is not exercised in purchasing iron for Admiralty or other use. The correspondent above alluded to expresses the fear that if the Admiralty continues its efforts to buy cheap steel, there may be another repetition of the "defective bayonet" affair or something worse.

ROUND STEEL FOR SCREWDRIVERS.—Why a screwdriver made from a flat bar of steel instead of a round rod, or one that is hexagonal in cross-section, should be preferred by a workman, can only be accounted for by the facilities that are offered by the flatness of the bar, in applying the forceps to assist in the torsional strains from the wrist. Perhaps it is to aid in the manufacture, as the round bar needs to be drawn out at the points, and is more difficult to secure in the handle. If not, there must be something gained in the way of leverage, or using as a lever in prying the work apart and many other applications for which the screwdriver was not intended. If a round bar of steel cannot be held securely in the handle of the driver, or a round blade be fastened strong enough to drive a screw with, the bar itself can be twisted to form both the blade and handle, by drawing out one end for the screwdriver, leaving enough length for the blade, then with a twist of one or more turns a well-formed handle is made with an eye or opening for the use of a bar when special strains are required. The loose end is brought down on the blade where the ferrule of the handle should be, and twisted closely round the shank. This class of a screwdriver is being introduced on the English market, and with the exception of the twist around the shank, which should have some of the properties of a weld, must make a very substantial tool.

DRILLING VS. PUNCHING IRON.—If the punch was boycotted in every carriage shop, this last means of getting rid of an objectionable article would contribute a little to the benefit of mankind. There was some excuse for using the punch before the days of twisted drills and improved drilling machines; now there is none, as the time necessary to drill through most irons that have to be punctured in a carriage shop is too slight to serve as an excuse for doing so much damage as is done when the punch is used. Driving the punch through a piece of iron weakens the fibers to a greater or less extent, it bulges when the metal is not very heavy outside the holes. The drill, on the contrary, cuts away the metal and leaves the iron around the holes intact. Some use punches because they want square holes for the bolt head; when a full square is necessary it is better to drill and then square up than to punch, but for ordinary use a square corner cut by a file into one side, and the three corners of the bolt filed away, is quite as satisfactory as a full square hole, and much better so far as the iron is concerned.—*Coach, Harness and Saddlery*.

SMALL SAW TEETH.—Speaking of small saw teeth, the *Boston Journal of Commerce* says: "The smallest teeth for a circular saw are not cut on the smallest saws. The saws for cutting rails by the abrasion process have no teeth at all, other than those formed by the particles of the saw plate. The saws for slitting gold pens are less than seven-eighths inch in diameter, but they have quite a respectable tooth to work with. The smallest saw we ever used was less than one-half inch across it, and was used for sawing veneering where the saw arbor rested on the work. The feed rolls would not admit of a larger saw, as a knife edge was intended to be used instead; but the cut from the knife would form side cracks whenever the work was dry, which would show badly when the thin stock was bent. This saw would remove, in the form of fine cuttings, what the knife was obliged to crowd to one side, and relieve the tendency of the saw to follow in the grain of the veneering; but where toothless saws are used they are driven with great speed and they require a large amount of power to drive them."

SCIENTIFIC PROGRESS.

The Birth Throes of the Moon.

The tidal wave, set up on the earth by the moon, reacts to a certain extent also upon the moon's orbital period. The moon is dragged forward in its path by the terrestrial tidal wave, as certainly as the tidal wave is drawn backward on the rotating earth by the moon, and this implies an enlargement of the orbit of the moon, and a recession of the moon from the earth. This process must go on until the day and the month both meet in a common period of about 1400 hours. But if this be the case, the moon must have been once much nearer to the earth than it is now. Prof. Darwin carries back his investigation in this direction to a time when the moon revolved about the earth in somewhere between two and four hours, and in a position where it was nearly in contact with the earth, and in which it was rotating in the same period—a state which may be looked upon as having been antecedent to the time when friction began its "work of grinding down axial velocity and expanding orbital range." The moon then started on its long spiral journey out from the earth. Prof. Darwin calculates that this start occurred not less than 54,000,000 years ago! But the most rapid rate of rotation in a fluid mass that would be consistent with spheroidal equilibrium is two hours and 20 minutes. One second of augmentation more than this in the rate of rotation would inevitably cause the rotating mass to fly asunder. The presumption is that the earth did fly asunder from overfast spinning, and that such disruption was coincident with what Miss Clerke speaks of as the "birth throes of the moon." Prof. Darwin, however, conceives that, in all probability, the lunar-terrestrial system is an exception among the bodies swayed by the sun, due to the circumstance that the moon is proportionally by far the most massive satellite known, and that the influence of tidal drag has been concomitantly great. No other satellite ever possessed tide-raising capabilities at all comparable with the influence which is exerted by the moon. The separation of satellites from their primaries essentially depends upon the attainment of a disruptive rate of rotation—an effect which may be prevented by the secondary effect of the additional tidal drag set up by the sun keeping down the velocity of the rotation of the primary below the velocity that would correspond with the actual point of disruption. The earth just escaped this degree of retardation, and hence the existence of its solitary satellite.—*Edinburgh Review*.

New Field for Investigation.

Condensing Smoke by Means of Electricity.

From Tyndall's experiments on the dust found in the air, Messrs. Clark and Lodge observed that a body at a higher temperature than its surrounding medium is enveloped in a thin stratum of air absolutely free from dust.

Mr. Lodge, of Liverpool, conceived the idea of studying this phenomenon, making use of electricity. In the course of his experiments he discovered that electrical discharges produced at high tension by a static machine possessed the property of condensing dust and smoke of all kinds.

This was not slow in finding a ready application in metallurgy, for condensing the dangerous fumes and dust of lead, dust in factories where that metal was largely used. The results secured were remarkable, and the attention of students was particularly called to this new method of treatment, because it had a twofold bearing—on the health of the workmen and on the economy of the process.

A contemporary says the experiments of Mr. Lodge are of that class which will in time become classical. He prepared especial devices for conducting his experiments, by which the effect of the electric discharge upon smoke and dust might be readily observed. He constructed a glass cylinder within which were placed two electric combs opposite to each other and at such distances apart as would admit of the ready passage of the electric spark from the positive to the negative comb. These combs were connected with the opposite poles of an electrical machine. The cylinder was placed over any convenient smoke or dust creating device, from which the smoke or dust ascended to the cylinder to be then acted upon by the electric spark or current.

German tinder, for instance, is put into the furnace. The thick smoke which it produces passes through the apparatus. If the electrical machine is now put in motion until the sparks pass between the combs, immediately the smoke becomes agitated, and in a little while will disappear by condensation, while the cylinder becomes as transparent as before the experiment.

The smoke of German tinder can be advantageously replaced by that which is produced by the combination of hydrochloric acid and ammonia. The white thick smoke of hydrochlorate of ammonia condenses very rapidly on the electrified combs. Tobacco smoke is very quickly and easily condensed by means of this device.

The phenomena are very remarkable, and appeal at once to the eye, the artisan, the medical man, etc., and at once opens up a new, useful and interesting field for investigation.

How Does the Brain Work?

How does the mechanism of the brain really act? I believe the true answer to this question is the one most fully given by M. Ribot, and never yet completely accepted by English psychologists. It acts, for the most part, as a whole; or, at least, even the simplest idea or mental act of any sort is a complex of processes involving the most enormously varied brain elements. Instead of "dog" being located somewhere in one particular cell of the brain, dog is an idea—audible, visible, legible, pronounceable—requiring for different modes of its perception or production the co-operation of an enormous number of separate cells, fibers and ganglia.

Let us take an illustration from a kindred case. How clumsy and awkward a supposition it would be if we were to imagine there was a muscle of dancing and a muscle of walking and a muscle of rowing and a muscle of cricketing and a muscle for the special practice of the noble art of lawn tennis! Dancing is not a single act; it is a complex series of co-ordinated movements, implying for its proper performance the action of almost all the muscles of the body in different proportions and in relatively fixed amounts and manners. Even a waltz is complicated enough, but when we come to a quadrille, or a set of the lancers, everybody can see at once that the figure consists of so many steps forward and so many back; of a bow here and a twirl there; of hands now extended both together, and now held out one at a time in rapid succession; and so forth throughout all the long and complicated series. A quadrille, in short, is not a name for one act, for a single movement of a single muscle, but for many acts of the whole organism, all arranged in a fixed sequence.—*Popular Science Monthly*.

A NEW EDIBLE VEGETABLE.—We expect that every year will bring a number of new varieties of well-known vegetables. Indeed, it would be a poor year if the English seed-growers did not give us at least half a dozen new peas or new names, but to have an entirely new vegetable added to the list is something noteworthy. The fact that this novelty is offered by a house of world-wide fame indicates that the new plant has some merit. The plant in question is *Stachys affinis*, which is a native of North Africa; it belongs to the mint family, and, what is unusual in that family, produces fleshy, tuberous roots which are the edible portion. The *American Agriculturist* says: The tubers are dressed like string beans, or fried in the form of fritters, and are said to make an excellent pickle. When freshly dug the tubers are pearly white, but upon exposure to the air they become blackened; hence it is advised to dig them only as wanted for use, or if dug in advance, to keep them covered with earth. *Stachys affinis* is the botanical name, and we are given "Choro-Gi," as a synonym, probably the name by which it is known in its native country. The plant is said to be very hardy, and to produce abundantly without special cultivation. Whether this will be a useful addition to our list of vegetables can only be ascertained by trial in various parts of the country; at present, it looks as if it would be an amateur's or "fancy" vegetable, rather than a regular crop for market.

PECULIARITY OF TORNADOES.—A resident of Minnesota, who has seen several severe tornadoes, says that their most peculiar feature is the singular sucking movement. Buildings are sucked up into the clouds entire, and come down soon in fragments. After the great Rochester tornado, a farmer 12 miles from town found an uninjured marble-top table in his field. Another found a very large sheep that had come from no one knew where, and had been deposited in his yard unhurt. The Minnesota man further said that he had seen a board into which wheat straws had been driven until they stuck through on the other side.

STANDARD OF LIGHT.—Professor John Trowbridge, in objecting to the light emitted by a surface of platinum at the point of solidification, adopted by the Paris Conference as the standard of light, contends that a better one might be found in an incandescent strip of platinum radiating a definite amount of energy, this energy being measured at a fixed distance, which will best agree numerically with the absolute system of measures now universally adopted in heat and electricity.

PASTEUR discovered that when milk was heated for a short time at 172°, and then suddenly cooled, it kept sweet much longer than the unheated milk. Dr. J. Van Geuns finds that this treatment disables and destroys most of the lower organisms in the milk, so that they are only able to revive when the conditions of temperature are extremely favorable.

A STRANGE SUBSTANCE has been found in Ellijay, Georgia, and is thus described by the *Courier* of that place: It is a yellow substance, very much like beeswax, and when shaved off with a knife it rolls up like beeswax. There is nothing about it that burns, but when heated it becomes hard as flint. It is a kind of rock, but nothing like it has ever before been seen.

EFFECT OF SUNLIGHT.—It is a remarkable fact in relation to the chemical action of the solar rays that cinchona trees growing in hot-houses develop no quinine in their bark,

American Tin at Last.

Within two weeks a new American industry will be born and American tin will make its bow to the commercial world and begin a vigorous competition with the foreign article. Almost three years have passed since the first deposit was discovered in Pennington county, Dakota, among the Black hills. To-day the Harney Peak Tin Mining and Milling Company has almost ready for operation a mill run by a 200-horse power engine, capable of reducing in its powerful embrace 200 tons of tin ore daily, and 100,000 tons of that ore have been opened up and are now awaiting the ordeal.

A specimen pig, said to be the first ever made in the United States for strictly commercial purposes, has been placed on exhibition at the Metal Exchange, and at the New York Metallurgical Works, on Washington street, may be seen a monster specimen of the ore, weighing 9000 pounds, which is destined to astonish John Bull in his own bailiwick. This specimen was blown out of a mass of ore taken from a tunnel in the Etta mine, on Tin Mountain, that was estimated to weigh 20 tons.

How rich the deposit is may be judged from the fact that the treatment in the metallurgical works of five tons of average ore from the Etta mine resulted in the production of 51 pounds of metallic tin to the ton—a considerably higher per cent than is shown by any mine in Cornwall. Moreover, it is said that the deeper the workings go the greater is the per cent of metallic tin to the ton.

Nor is the Etta group of two lodes the only source of supply owned by the Harney Peak Company. Thirteen miles away is the Hill City Group, comprising 43 lode claims, containing true fissure veins of unusually rich tin ore. Here a small mountain of mined ore is piled on the dumps, awaiting the completion of the mills.

What is to be the future of this industry? We import in round numbers \$6,000,000 worth of tin yearly, and the consumption is increasing as fast as new uses for the metal are being found. The mines of the Old World are nearing exhaustion and the new supply must be American. The richness of the deposits and the peculiar natural advantages in the matter of water and facility of transportation about the district reduce the cost of production to ridiculously low figures—the estimate being one dollar per ton for mining ore, and one dollar per ton for milling it.

With all these advantages for facilitating a large output, the promoters believe that the market cannot be materially affected for five years to come. In the meantime it is proposed to still further invade the English domain and enlarge the American field by the manufacture of tin plates, and a syndicate of prominent Pittsburgh iron men, after a thorough investigation into the causes that made earlier attempts unsuccessful, are preparing to make tin plate from the Harney Peak product, so intrinsically superior that the English article will be unable to compete with it.—*New York Ironmonger*.

A NEW DISTRICT.—Several months ago A. P. Rhodes and Geo. Plant went out prospecting and discovered some good prospects in the southeastern part of Death Valley, about eighty miles northeast of Calico. The district has been named Hope Springs, and the claim on which they are working, Black Metal mine. The mines are situated seven miles from a good spring. A shaft has been sunk 15 feet, and the ore taken from the same samples well. Mr. Rhodes recently brought to the mill at Daggett 1200 pounds of ore from the mine, the pulp assay of which went \$132.47 to the ton. From present indications the mine will yield considerable ore that will average \$100 to the ton. The belt in which this mine is located has been prospected for two miles, and ore discovered at intervals its entire length. The owners of the group are A. G. Rhodes and George Plant, who own one-third each; Mrs. Humiston and her nephew, William Kelly, who own the remaining one-third. The owners of this new find are pleased with their prospects, and will prosecute developments as long as they show up as well as at present.—*Calico Print*.

N. CLARK & SONS, proprietors of the Pacific Pottery Works, Sacramento, the oldest clay workers in the line of pipe and fire-brick upon the Pacific Coast, are building branch works at Alameda Point, near Alameda county. The foundations for the buildings are laid. The structure will be 260 by 110 feet, and four stories high. Steel boilers will be put in of 150-horse power, with engine to correspond. The new works are for the express purpose of manufacturing fire-brick, and perhaps at a later date other clay products.

NEARLY 60,000 barrels of lime have been shipped, by steamer alone, from Santa Cruz during the past year, of which amount Meere, Davis & Cowell have shipped about 50,000 barrels, all of which has gone over their own wharf—about 35,000 barrels to San Francisco and about 15,000 barrels to points on the Southern coast. During the same period the I. X. L. and the Holmes companies have shipped the remaining 9000 to 10,000 barrels from Felton over the railroad wharf to ports South.

To CLEAN red brick floors, rub them with a brick of the same color, moisten with a little warm milk and water, and wipe dry with a soft cloth.

USEFUL INFORMATION.

Electro-Deposition of Steel.

The *Manufacturer and Builder* gives the following: For this purpose many formulae have been proposed, the principal use for the product being the coating of copper electrotypes, for printing, with a steel surface, to give them better wearing qualities in the press. The baths formed of the double sulphate of iron and ammonium, or the sulphate of iron and chloride of ammonium, appear to be best adapted for the purpose. The first of these is prepared either by making a saturated solution of the crystals of the double salt, or by mixing a saturated solution of the two salts (the sulphate of iron and the sulphate of ammonium) in their equivalent proportions; or by precipitating a solution of the sulphate of iron with carbonate of ammonium, and dissolving the precipitate by the careful addition of sulphuric acid, avoiding an excess of the acid. The sulphate of iron and chloride of ammonium bath is prepared either by mixing the two salts together in their equivalent proportions, or by dissolving in a saturated solution of the sulphate of iron as much chloride of ammonium as it will take up at the ordinary temperature. All of these baths should be made as concentrated as possible, and should be maintained quite neutral. For an anode, use a plate of rolled iron, with at least eight times the surface of the article to be coated. The current should be of moderate strength. The deposited metal is as hard as cast steel, but very brittle. It may be tempered by annealing. With regard to the electro-deposition of this metal, it may be said that all the supposed advantages to be obtained from iron (or steel) surfaces on copper or other metals or alloys are practically gained by the use of a nickel coating, so that the importance attached to these processes a number of years ago, before nickel-plating came into vogue, has disappeared. Many electrotypes coat their copper printing plates with nickel, for the double purpose of adding to their durability in the press and of preserving the integrity of their colored inks, some of which—notably vermilion—act chemically on copper, producing a brownish color on the printed page, due to the formation of a sulphide of copper.

A SOMETIMES VALUABLE HINT.—Sometimes even a very slight knowledge of natural history is of great practical use. As an illustration, we give the following, related by a naturalist. A gentleman, making a call at the house of a friend, was astonished to find the rooms and passages in confusion; and, on inquiring the cause, was answered: "Oh, we are very much annoyed here; a rat has come to finish his existence under the floor of our large drawing-room. We do not know the exact place, but we cannot endure the stench any longer; so we have removed the furniture, rolled up the carpets, and called in the carpenters, who are just beginning to take up the floor." "Now, don't be too hasty," said the visitor; "you need not pull up more than one board. I will show you what I mean presently; and meanwhile, shut down the drawing room windows, and close the door." He then stepped down into the garden, walked around to the horse stables, and after a few minutes' absence came back to the drawing-room with both hands tightly clasped. Placing himself in the center of the drawing-room, he opened his hands, and out flew two large blue-bottle flies, and buzzed around the room for a second or two. But presently one of them alighted on a certain plank of the floor, and was almost immediately followed by the other. "Now, then," said the visitor, "take up that board, and I'll engage that the dead rat will be found beneath it." The carpenters applied their tools, raised the board, and at once found the cause of the unpleasant smell.

CARVED GLASS.—At one time glass encompassed gold, not only in value as a material, but in forms of vases and drinking vessels wrought into various patterns by means of wheels and points. An article of the kind was considered a worthy present for a king. Glass carving is a branch of the art of carving precious stones began by the lapidary savage and improved with more or less ability by workers in archaic times and earliest civilizations. In the Greek and Roman periods, when the glyptic art was encouraged as a whole, carving on glass may be said to have reached its zenith. Perhaps it is to the latter Greeks and Romans that we are indebted for the finest work of the kind. Colored glasses were generally preferred to glass of only one color for carving, and at the present time cameo work, or relieve, in one color or more than one, upon ground of a different color, is growing in favor of the educated and wealthy at home and abroad. To England is due the honor of reviving the art of carving glass.

GIVE THE BOYS TOOLS.—Give the boy tools, and let him find out for himself whether he has got any mechanical taste or not. Do not discourage him, as parents are apt to do, by saying: "Oh, it is no use for you to try to do anything with tools. I never had any taste that way, and, of course, you have not." If a boy finds he can make a few articles with his hand, it tends to make him rely on himself. And the planning that is necessary for the execution of the work is a discipline and an education of great value to him. The future welfare

and happiness of the boy depends on the surroundings of his youth. When he arrives at that period in his life when he is obliged to choose what profession or what line of business to follow, it is highly important that he should take no false step. And if in his youth he has cultivated a taste for any particular branch, the choice of a profession or business will be made more easy. We hope to see manual training in the public schools, for this hand, as well as the brain, should be taught, that they may both be of more use to each other.

SOAP TO CLEAN STEEL.—A soap for cleaning surgical instruments, and other articles of polished steel which have become flecked with rust by exposure in showcases, is made by adding precipitated chalk to a strong solution of cyanide of potassium in water until a cream-like paste is obtained. Add to this white castile soap, in fine shavings, and rub the whole together in a mortar until thoroughly incorporated. The article to be cleaned should be first immersed, if possible, in a solution of one part of cyanide of potash in four parts of water, and kept there until the surface dirt and rust disappear. It should then be polished with the soap, made as above directed. Articles so treated look as "good as new."

LACE WORK ON GLASS.—An inventor of Metz has produced the effect of lace work on glass, and the process is thus described: After the articles in question have received a slight coating of turpentine, a metal or paper stencil is applied, which represents a lace pattern, and the objects are strewn with a fine powder of asphalt and mastic. The stencil is then removed with care, and the glass is heated to such a temperature as will melt the powder. The acid, to the action of which the glass is then exposed for thirty or forty minutes, cannot affect the covered portions, but only acts upon those which have remained free. This process has the advantage of being very rapid in its effects.

TO SOFTEN HARD PUTTY.—To soften putty that has become hard by exposure, so as to remove it easily from a sash, take one pound of pearlash, and three pounds of quicklime; slack the lime in water, then add the pearlash, and make the whole about the consistency of paint. Apply it to the putty on both sides of the glass, and let it remain for 12 hours, when the putty will be so softened that the glass may be taken out of the frame with ease.

GOOD HEALTH.

VITAL STATISTICS OF THE NATION.—It appears from the latest report of vital statistics, just completed for the census of 1880, that there were 756,893 deaths during the census year—classified as follows: Unknown causes, 37,183; consumption, 91,270; pneumonia, 63,053; diphtheria, 33,143; heart disease, 26,065; cholera infantum, 24,983; still births, 24,876; typhoid fever, 22,854; malarial fever, 20,231; croup, 17,966; convulsions, 17,844; scarlet fever, 16,388; dropsy, 14,788; debility, 14,619; old age, 14,168; paralysis, 13,907; dysentery, 13,427; cancer, 13,068; enteritis, 12,640; diseases of the brain, 12,280; whooping cough, 11,064; bronchitis, 10,984; inflammation of the brain, 10,903; diarrhea, 10,829; apoplexy, 9658. The ravages of that terrible disease cancer appear very prominent in the classification, averaging one death in every 57. The mean annual increase of births over deaths was 878,522, or the birth rate equal to 36 per 1000. The United States in the census year had a comparatively low death rate and a high birth rate. The death rate is shown to have been higher in the colored than in the white population; in the foreign element than among the whites of American parentage; in the cities than in the rural districts.

INTEMPERATE EATING.—If it is legitimate to estimate a part of the criminality of whiskey-drinking by the results, by crimes committed while under its influence, it is equally legitimate to refer much of the irritability of the dyspeptic to mince pies, new bread, rich pastry, indigestible foods in general, so vitiating the stomach, and through it the whole nervous system, that good health and physical comfort are impossible. Neuralgia is certainly results from the excessive use of tea and coffee, as drunkenness does from whiskey. Mental obscurity may as well result from gluttony as from dissipation, while it may as certainly be regarded as a sin to be a dyspeptic as a drunkard, both resulting from excesses, the one from intemperance in eating, the other from drinking. Both are alike avoidable, for the consequences of which we are personally responsible.—*Medical World*.

SOOTHING SYRUP AND THE OPIUM HABIT.—There is no better way to have the way to the terrible opium habit than the practice of many mothers in making a too free use of the well-known "Mrs. Winslow's Soothing Syrup," which is composed of simple syrup, anise and morphine. This syrup is usually given on the slightest provocation or appearance of uneasiness in infants, and often when no provocation appears, given merely to continue sleep and quiet so that the mother can keep on with her work, or leave the baby with a nurse while she goes to call on a friend. This syrup should only be given when all other methods of allaying uneasiness fail.

A CHARM AGAINST DISEASE.—Many people fall ill of disease simply through fear of it. The imagination has a powerful influence on the human body. One can very easily imagine himself to be catching cold at the sight of an open window, when if he did not know the window was open, or was not afraid of its effects, he would escape the cold. Doctors understand this secret, but they do not impart it to their patients. Most invalids, real or supposed, would be angry if a physician would say to them, "Nothing ails you, you only think so." They prefer to think themselves sick, and in time they really become so, for nature, though she struggles hard, cannot stand everything. Too many drugs will finally destroy her healing power. These people who love to have a box of white pills in bottles, and a little book, all kept in some handy place, so that when a friend who has eaten too much dinner says, "Oh, I am fearfully nervous!" they may run for the little book, look for "nervousness," and administer so many pills of hryonia. When they have a headache, instead of dieting or eating more moderately, they take several drops of some nice poison. They trust nothing to nature, but call in a doctor for every little ailment, when fresh air, exercise and strict temperance in eating and drinking is all they need.

TOBACCO BLINDNESS.—The anti-tobacco people ought to have their attention called to the fact that "tobacco-blindness" is becoming quite a common affliction. At present there are several persons being treated for it at one London hospital. It first takes the form of "color-blindness;" the sufferers who have smoked themselves into this condition being quite unable to distinguish the color of a piece of red cloth held up before them. That is the popular medical test, though there is also a more scientific one. Eventually the victim to "tobacco-blindness" sometimes loses his eyesight altogether. Although smoking is to a large extent the cause of the malady, and so gives it its name, heavy drinking is also partly responsible. Unless the smoking and drinking go together the "tobacco-blindness" is not serious. A proof of this is that if a doctor has a case of it in hand, he always insists on abstinence, when, as a rule, the sufferer gradually regains his sight.—*St. James' Gazette*.

DARKENING ROOMS.—The American custom of darkening the rooms where visitors are received has arisen from the natural cause of the peculiar brightness of American skies. Glare is always distressing to sensitive persons, and American glare is phenomenally brilliant at times. Not even the sunlight of the tropics is more penetrating than this steady, blinding light; white, blue, steel in its strange atmospheric quality. To subdue this brilliance, to tone down the reflection, is the aim of most American women who have an atom of vanity in their compositions, and hence the darkened rooms where all that is beautiful and artistic may lie in shadow, though touched here and there by faint glimmers of firelight, or the tender glow from a silken window drape. American drawing-rooms have until recently been victims of "cross-lights," which destroyed the artistically blended colors in the furniture and ruined the pictures and decorations on the walls.

COFFEE-EATING HABIT.—A correspondent of the *Medical and Surgical Reporter* mentions the case of a young woman of 22 who had acquired the habit of eating roasted coffee beans. Though the habit was only of four months' standing, she had eaten as much as half a pound a day, and had only decreased to four ounces per day on the earnest solicitation of friends. The effect on her health had been that she became pale, sallow and nervous; the pulse weakened, the stomach got out of order, and, among other symptoms, there was a marked dyspnea in going upstairs. An attempt to stop the habit was followed in a few hours by intense nervousness, trembling and a strong desire for coffee.

A PASTEUR LABORATORY FOR NEW YORK.—There is the prospect of an establishment in New York of a branch of Pasteur's laboratory, to which Americans in danger of hydrophobia may hereafter resort instead of traveling to Paris. Dr. Valentine Mott, son of D. B. Mott, one of the most noted surgeons of New York, has been over to Paris to study Pasteur's methods, and brought back with him a stock of rabies virus and an inoculated rabbit. The rabbit died Saturday. The next day Dr. Mott and his father inoculated another, and are now prepared to start a hospital as soon as they can find proper quarters.

PHOTOGRAPHY IN MEDICAL PRACTICE.—Some novel and interesting applications of instantaneous photography to the study of the movements of the heart and intestines have recently been made by Dr. W. G. Thompson. Photographs of rabbits' pigeons' cats' and frogs' hearts were made, showing the action more clearly and accurately than is possible by other methods. In addition to the value of such in physiological teaching, the most practical application of the method will be the illustration of the changes in the form of the heart and intestines produced by drugs.

TURPENTINE IN LOCKJAW.—Warm a small quantity of turpentine and pour it on the wound, no matter where it is, and relief will quickly follow in an attack of lockjaw. So it is said.

Passing Events.

It is pleasant to note that silver has advanced a little from the very low price prevailing of late. The rise is not very much, but that the downward tendency has been checked is encouraging.

Considerable prospecting is now going on all over the coast, the more mountainous regions now being freed from snow. The streams are running full from the melting snows, and all the mills have plenty of water.

There is a tendency apparent among miners just now to go north rather than south from here. Many have gone to Alaska, and others are going to Oregon and Idaho. The field for prospecting in this State is, however, by no means thoroughly covered, and our northern counties are being pretty well searched this season.

In Arizona the Indian trouble is still keeping mining matters back. It is difficult to enlist the aid of capital in the Territory while Indian raids may be expected. Arizona will never reach its full tide in mining prosperity until the Indian question is satisfactorily settled.

A fine body of coal has been found at the head of the Estrella plains, San Luis Obispo county.

Mineralogy at the University.

At the last meeting of the Board of Regents of the University of California, on recommendation of the Finance Committee, \$1250 was appropriated for the purchase of mineralogical specimens from the Royal Saxon Mineral Depot for the university museum.

It was also resolved to create a separate department of mineralogy, petrography and economic geology in the university, and A. Wendell Jackson was appointed professor of the department. Professor Jackson has for a long time been instructor in the departments mentioned, and now obtains the professorship. He is an enthusiast in his chosen branches, and is recognized as a very able man. He is not content with mere lecture work, but has constantly pursued original research, and some of his investigations have been of the highest interest and value. The museum of economic geology, the founding of which is due to his efforts, is already large and receiving valuable additions. It renders possible a course of instruction in ore deposits, which is of essential importance to those who intend to pursue the profession of mining engineer. Moreover, the ore deposits of the Pacific Coast are being brought together for the first time in one institution, where they can be subjected to careful and critical comparative investigations, in order that the laws of their occurrence may, as far as possible, be determined. The locality, form, thickness, dip, strike, wall-rock, etc., of every ore deposit on the coast are carefully recorded as soon as accurate information on these points can be obtained.

In petrography the rocks are determined by means of their microscopic sections; they are then arranged systematically and geographically, so that as the collection becomes more complete the geographical distribution of the rocks of the Pacific Coast will be known with great accuracy and detail. The collection of mineralogy, also under Prof. Jackson's charge, is fully arranged and very large.

Prof. Jackson lectures twice a week at the university on crystallography, mineralogical terminology and descriptive mineralogy, and careful examinations of specimens are allowed illustrating every form of occurrence of each mineral. He also instructs in the determination of unlabeled minerals by means of their physical properties only, the apparatus used consisting of penknife, pocket lens, streak plate and magnet; all easily carried in the vest pocket. The object of this course is to give the student sufficient familiarity with the most commonly occurring minerals of economic and geological importance, to enable him to recognize or determine them in the field.

The course of instruction in petrography covers the following ground: The different methods of rock investigation; rock texture and structure; different forms in which rock masses occur; classification and nomenclature; origin of rocks; change and decomposition of rocks. The course is fully illustrated with hand specimens and rock sections.

The course in microscopic petrography embraces instruction in the theory and use of the microscope, investigation of rock sections, micro-texture of rocks, etc. In economic geology the instruction includes a general discussion of the form, structure, composition and origin of different kinds of ore deposits, followed by detailed descriptions of the ore deposits of this country and the specially instructive foreign deposits.

Prof. Jackson's work is not changed by his promotion. We are glad to see him given the title, however, for he deserves it, and it is another evidence that the mining department of the university is being more fully recognized by the Regents.

PRACTICAL HYDRAULICS.—Mr. P. M. Randall's book on this subject is now printed and bound, and ready for sale by Dewey & Co., 252 Market street, S. F. As a convenient work of ready reference for miners, irrigators, or hydraulicians, it is not excelled. The matter is fresh, concise, and well arranged, and the index makes it easy to find the answer to any question in this branch readily.

THE 120th dividend of the Ontario Mining Company of 50 cents per share is payable on the 31st ult. The total of the five months of 1886 is \$375,000; grand total to date \$7,500,000. The stock is quoted from \$23.50 to \$29 per share.

The Selby Smelting and Lead Company.

The new works of the Selby Smelting and Lead Company, at Port Costa, are now entirely completed, and they have almost finished "cleaning up" the old works at Black Point. A great deal of the old material had to be worked up, and now that this is done the company is making more prompt returns than ever. On the 27th of last month the capital stock of the company was increased from \$200,000 to \$600,000, which is fully paid in, and they have a large surplus over and above this. The very unpleasant litigation in connection with the Albion-Richmond mining companies affair has all been satisfactorily settled. Arrangements have lately been made with the Bank of California, Wells, Fargo & Co., and Nicholas Luning, which secure to the company the advantage of having men closely identified with them who have experience and knowledge of the business, and who, themselves, control the larger portion of the gold and silver product of the coast. Therefore, these business relations are pleasant and convenient.

It is gratifying to know that the business of the company has greatly increased of late, with the increase of facilities afforded by the new and more extensive plant. Ore and bullion is now coming in from new districts which have heretofore been shipping entirely to the East. Montana and Washington Territory are now shipping more or less material here, which has not before been the case. Arrangements have been made with the railroad and steamship companies to increase this interest, which will add to the volume of business materially.

It is pleasant to note also that the bullion product from different sources is gaining in amount each year, as available statistics prove. The amount of silver coming to this city has doubled within the past two years. This shows that not only are the mines increasing their output, old mines are being worked vigorously, and new ones being developed, but that new channels and more extensive connections have been made, the result of years of work in the development of our home resources.

The Selby Company now have facilities for working everything in the shape of ore, bullion, etc., that is offered, so it is no longer necessary to ship ore or bullion East or abroad from this coast. The gradual enlargement of plant, and increase of business facilities, undertaken and accomplished by the Selby Company, show that they have every confidence in the future of our mining industry.

Comparative Trials of Quartz Mills.

In the PRESS of last week appeared a letter from Mr. Louis Blanding, of Sonora, Tuolumne county, on the comparative merits of stamps and rotary pulverizers in reducing quartz. In the course of his remarks Mr. Blanding made some statements and drew conclusions as to the power required in operating the Tustin mill and the work accomplished by it at the Oro Plata mine, Murphy's, Calaveras county, which are incorrect. It is evident he was misinformed concerning the results of the trials referred to. For the benefit of Mr. Blanding, as well as others, we will give the facts in the case, obtained from reliable authority.

At the Oro Plata mine 15 stamps of 750 pounds, 6-inch drop, 90 drops per minute, crushed 30 tons of quartz per 24 hours, through a 20-mesh screen. This requires about 22-horse power. Four Tustin mills, working on the same ore and using the same screen, crushed at the rate of 48 to 50 tons of ore per 24 hours. The four machines required 17.68 horse power, or 4.42 horse power each, measured by the Prony brake, counted from the water-wheel.

The working result on low-grade quartz shows that more than twice as much gold is saved by amalgamation from the ore crushed by the Tustins as that crushed by the stamps. The reason for this is that the stamps make a pulp containing 45 per cent of elimes, while the Tustin pulp contains only eight per cent.

We shall shortly give the details of these comparative trials, with such diagrams and drawings as will serve to fully illustrate the subject.

THE loss by the fire at the hoisting works of the Grand Central mine, at Tombstone, will be \$250,000. The shaft is a total wreck. About 150 men have been thrown out of employment.

The Late Walter A. Skidmore.

Walter A. Skidmore, who has for many years been identified with the mining interests on this coast, and particularly in this State, died at his residence in this city on Saturday last. Mr. Skidmore was formerly a printer, but has not followed that occupation since 1871 or 1872. He published in the latter year a work on mining law. While R. W. Raymond was United States Mining Commissioner, and published an annual report, Mr. Skidmore was his deputy on this coast and gathered a large part of the material published in the reports. The main portion of the chapters on California were written by him, and he compiled and prepared the statistics of production also. On the discontinuance of these reports he was employed by the Director of the U. S. Mint to assist in the preparation of the material on California for that annual report. In the volume published last year were several well-written and valuable articles from his pen.

Mr. Skidmore has been for some years Secretary of the Miners' Association of California, and did a large amount of work in connection with the association while the debris suits were pending.

On occasions Mr. Skidmore has followed the business of reporting on mines. His familiarity with hydraulic and drift mines in this State gave him an experience that was valuable to his employers. In fact, he had a very intimate and accurate knowledge of mining affairs in California. Many articles from his pen have appeared in the PRESS from time to time during the past 12 years. He was a ready and forcible writer, possessing the ability to state his ideas clearly and in a terse and easily-comprehensible manner. He was one of the few men on this coast who has devoted his pen entirely to the development of the mining industry.

Mr. Skidmore had a deserved reputation for honesty, integrity and ability. He made friends wherever he went from his genial disposition and gentlemanly demeanor. He was a very generous man, possessing also other qualities which endeared him to all his associates. For some months past he has been confined to his room by the illness which resulted in his death, which will be regretted by a large circle of friends and acquaintances.

Mining Accidents.

An accident occurred at the Badger mine, Grass Valley, on Wednesday, whereby Patrick Mullen, one of the oldest miners in the district, received injuries that may terminate fatally. He was one of a party who have the contract for pumping the water out of the mine, and although there were 22 other men in the building at the time, no one has seen how the accident occurred. When found he was unconscious. It is believed, from appearances, that he went to cross the bob pit, but was not quick enough, and was struck by the bob and thrown into the machinery below him. His left foot was badly crushed above the ankle by the cog of the wheel, and the skin and muscles were all torn from the outer part of the left thigh bone. Besides this he had the two bones in his right leg broken, and received other severe injuries from which he is not expected to recover.

A Times Leadville special says: A cave occurred in the Colonel Sellers mine, in California Gulch, at noon Wednesday, in which Joseph Pretti, Louis Miller, H. Hitchcock and Louis Pretti, four miners, were caught. The men were working in a stope 300 feet high, putting in timber, and a heavy mass of ore caved in upon them, filling the stope. A gang of 150 men are working with all energy, but despair of recovering the bodies, as the water is rushing in so fast and ore keeps falling in upon them, so that it is hardly possible that the remains will be reached to-day.

VIRGINIA CITY newspapers complain that business there is rendered dull by the habit which miners and mechanics have got into of sending to San Francisco to make their purchases. Two hundred thousand dollars a month is disbursed in Virginia by the Comstock mines, but business was never so dull.

THE mills dependent on Virginia City mines are all busy. From good authority it is learned that there are undoubtedly more men employed in Virginia than there were four or five years ago.

A Curious Gold Mine—No. 3.

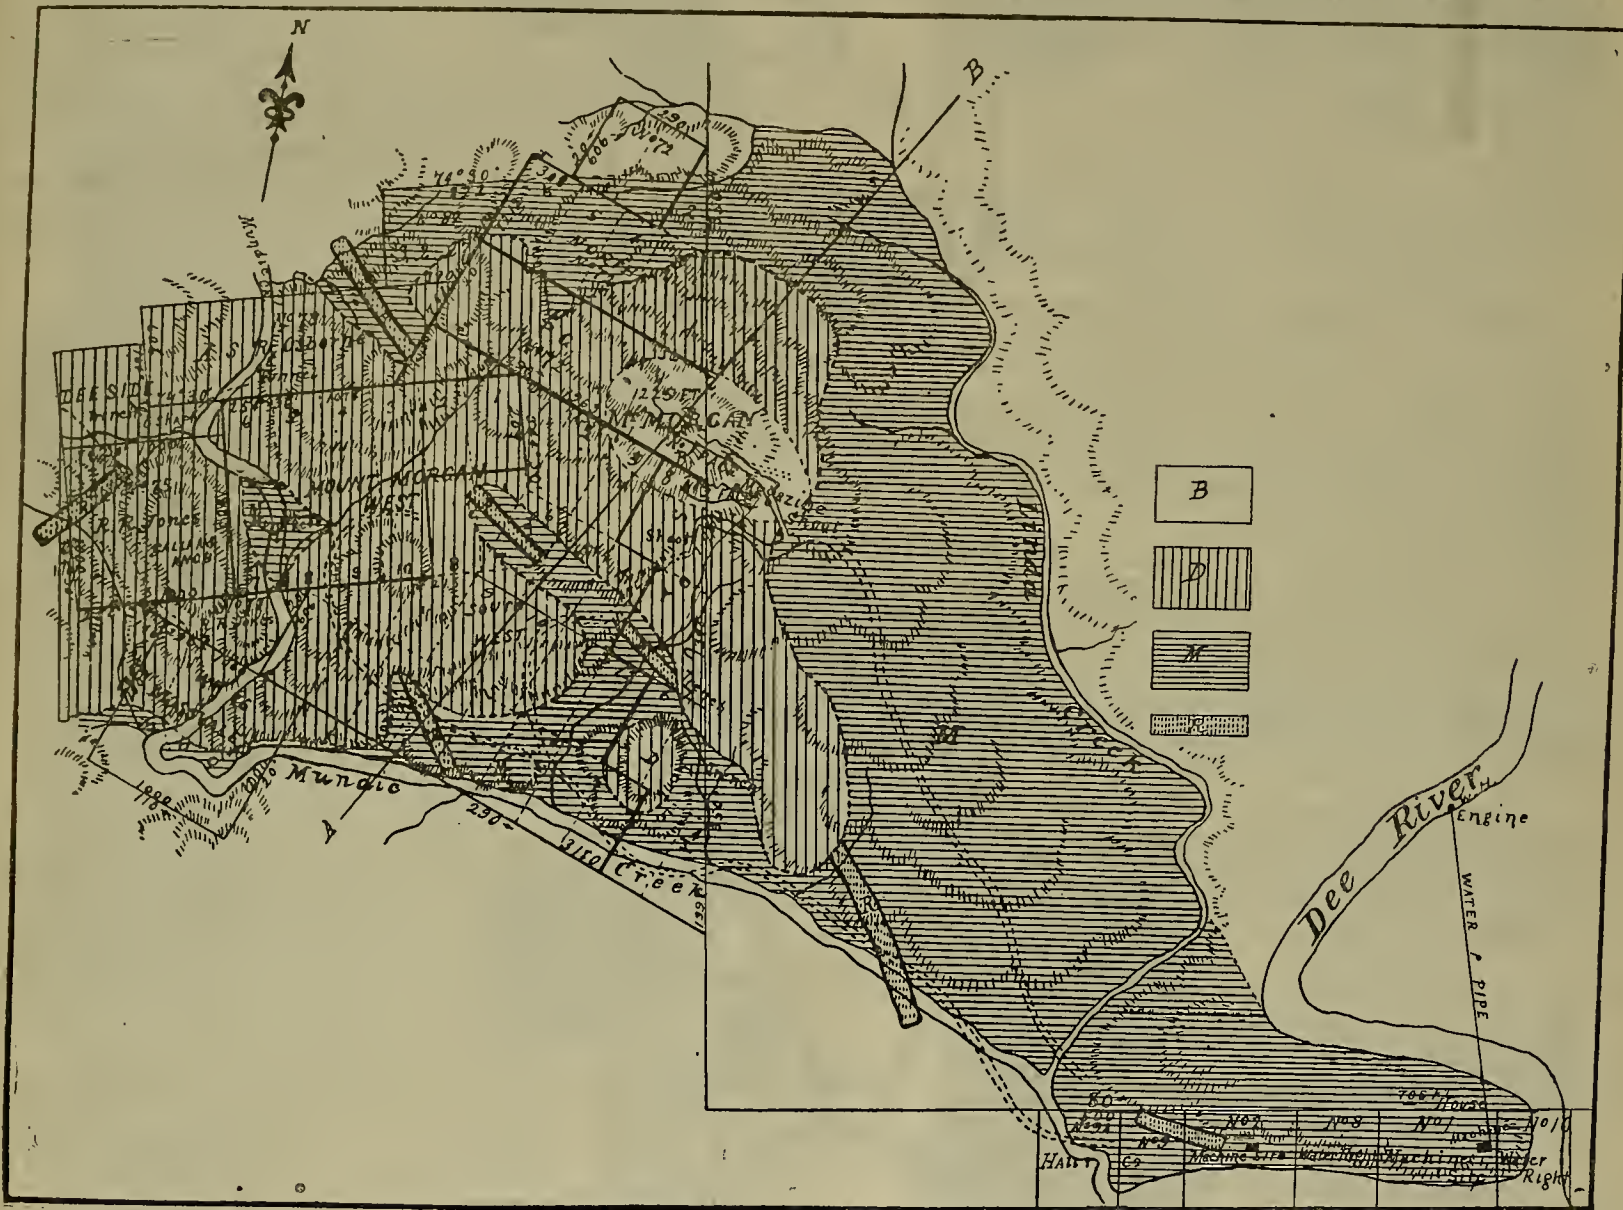

In the immediate vicinity of Mt. Morgan, the country rock consists of a bluish gray quartzite—a fine-grained siliceous sandstone, now more or less vitrified—full of minute crystals of iron pyrites and specks of magnetic iron ore, greywackes of the ordinary type, hard, fine-grained sandstone or mingled siliceous and feldspathic material, now somewhat indurated; and, lastly, occasional masses of shale, hardened to a flinty consistency, and a few belts of serpentine. As the stratified rocks in this particular locality appear to have been in thick beds, and as this metamorphism has gone a considerable length, it is not easy to be certain of either dip or strike. The stratified rocks are, moreover, interrupted and intersected in every direction by dykes and other intrusive masses of dolerite (itself altered by the substitution of viridite for

great blocks up to some tons in weight, with a stalactitic structure, as if the iron oxide had gradually filled up cavities left in the original deposit. The ironstone contains gold of extraordinary fineness, which, however, after a little practice, can be detected in almost every fresh fracture. The ironstone is more or less mixed with fine siliceous granules. Gradually, to right and left of the central mass, the silica more and more replaces the ironstone. It is a frothy, spongy or cellular sinter, sometimes so light from enlargement of air in its pores that it floats in the water like pumice. Fine gold is disseminated throughout this siliceous deposit as well as on the ironstone. Near the west end of the cutting is a vertical dyke of Kaolin, mixed with fine siliceous granules, passing into pure Kaolin, with some silicates of magnesia, including a fine variety of French chalk. Characteristic specimens from the upper cutting as-

the cutting ends with a mass of soft earthy aluminite. Prospects were obtained in every part of the cutting, with the exception of the siliceous earth. Good prospects were found in varieties of materials which miners would generally consider most unpromising.

Down the hillside, to the north, west and south, a similar deposit is everywhere met with; a frothy or spongy matrix, sometimes aluminous and sometimes siliceous, generally iron-stained and occasionally associated with large masses of red and brown hematite; but gold has as yet only been obtained from a few places away from the hilltop, though naturally there has been considerable prospecting wherever the formation resembled that of Mt. Morgan. Perhaps the deposit on the slopes is more aluminous and less siliceous, and contains less of iron oxides than on the hilltop; but these are the chief differences, and the formation has evi-

from which the spring was fed. The gold, and to some extent the iron, may have been dissolved out of the iron pyrites of such ledges as the Mundic reef, seen on Mundic creek; the gold possibly by chlorine produced by the contact of hydrochloric acid, derived from the decomposition of chlorides with manganese, which occurs sparingly in the form of pyrolusite along with the ironstone in Mt. Morgan. The deposit left by the thermal spring is evidently newer than the altered stratified rocks through which it hurst. In the presence of so much ironstone a precipitate for the gold need not be far to seek. Protoxide of iron was probably present in sufficient quantities to perform this important function, but it may have been aided by tannic acid derived from vegetable matter accumulated in the basin. Precipitation of the gold by tannic acid would accord better with the confinement of the gold to the basin or center of Mt.

PLAN SHOWING POSITION OF MOUNT MORGAN GOLD DEPOSITS.

its argillite or olivine), rhyolite and other igneous rocks; the intrusive masses apparently occupying as much space as the remnant of the original stratified formation itself. The country rock is traversed by ledges of the ordinary description, several of which contain gold.

Mt. Morgan itself, as described in the previous articles, contains gold in a very unusual—or quite unprecedented—formation. The form of the latter will be best understood by reference to the accompanying sketch, made from a plan based on surveys by Mr. T. Byerly, accompanying Government Geologist R. L. Jack's report.

Aneroid measurements give Mt. Morgan an elevation of 1225 feet above sea level. The mine is at the summit of the mountain, and is approached by a rather steep road. The work is carried on in two quarries or faces, one of which (No. 1) is designed to remove the top of the mountain, to pass it through the stamps, and the other (No. 2) to attack the auriferous quarry 100 feet below.

The central portion of the upper cutting is a large mass of brown hematite, generally in

sayed from four to six ounces and up to 10 ounces of gold per ton.

The shading on the plan corresponding to the lettered blocks represents the following: B, deposit of basin of hot spring; D, deposit of overflow from hot spring; M, metamorphic rocks; R, rhyolite dykes.

The lower or magazine face (No. 2) presents a sort of fanlike arrangement of its various materials. In the center is a hard (almost vertical) deposit of brown hematite in large "horns," with a mammillated botryoidal or sometimes reniform appearance. To the right (east) is a nearly vertical deposit of aluminous iron ore, followed by a mass of red hematite or large cellular bombs. To the east is a broad mass of loose iron-stained siliceous and aluminous material, which begins to lean eastward, like the outer feathers of a fan. A great mass of loose earthy hematite, another of brown hematite, weathering to iron-ore, another of red earthy hematite, and another of brown hematite in large ton blocks appear in succession, as the cutting is followed east. Near the east end of the cutting is a fine white siliceous earth, and

dently ore origin throughout.

After a careful study of the whole formation Mr. Jack came to the conclusion that nothing but a thermal spring, in the open air, could have deposited the material under consideration. The frothy siliceous sinter agrees in every respect with the deposits of New Zealand and Iceland geysers, and of the still more wonderful hot springs of the Yellowstone Park. The frothy and cavernous condition of the siliceous sinter of Mt. Morgan may be accounted for by the escape of steam while the silica was yet (after the deposition in the evaporation of the water) in the gelatinous condition so frequently observed in the deposits of hot springs. The aluminous silicates represent the familiar outbursts and flow of mud. The iron oxide appears to have been deposited in some cases along with the silica and alumina, and in others to have been deposited later. In some cases it may have been originally pyrites, as it now and then occurs in cubical hollows. Calcareous sinter is very common in siliceous springs, and its absence from Mt. Morgan must needs imply the local absence of limestones among the rocks

Morgan than precipitation by ferrous oxide and the occurrence of vegetable matter in the basin of hot springs is not uncommon.

THE tendency of silver in London is upward. The cause of the improvement is attributed in part to a refusal of the Indian Council to accept bids for drafts at the then current rates. The lowest quotation on record is 44½ pence per ounce, which was made about three weeks ago. On Wednesday, May 12th, the Indian Council met and allotted drafts at the lowest rate ever accepted for Government exchange in India. The quotations dropped from 45½ to 44½ in three days. The refusal of the Indian Council to accept bids of the lowest figure caused a marked improvement.

CABLE SUITS DISMISSED.—The several cases against the Market, Sutter, Presidio and Clay Street Railroad Companies instituted by the Cable Railroad Company, and which have been pending in the United States Circuit Court for several years, have been dismissed by stipulation.

Practical Hydraulics.

By P. M. RANDALL.

A Book for Civil Engineers, Miners, Millmen, Hydraulicians, Mining Engineers, and Irrigators.

This new work is by one of the most experienced hydraulicians of the country. It abounds with useful tables for ready reference, in which the results of abstruse calculations are all placed in a form so that one can find what he wants in a moment. For the engineer the principles, formulae, coefficients, etc., are given; and for those not familiar with higher mathematics, examples, rules, and tables are prepared. Thus the needs of the scientist and the practical miner or millman are each met. It is the most complete work on the subject yet published, and is specially applicable to the Pacific Coast.

Table of Contents.

The following brief abstract of the contents will give an idea of the branches of the subject treated:

General Plan; Discussion of the Principles of Hydraulics; Rules Deduced from Formulae Obtained; Examples and Calculations; Extensive Tables for Ready Reference; Fundamental Laws of Hydraulics Demonstrated, and Expressed in Formulae and Rules; Flow of Water through Openings; Weir Coefficients; Triangular Weirs; Flow of Water over Quadrant Weir (tabulated); Application of Tables; Submerged Orifices; Flow through Orifices in Thin Partitions; Tables and Applications; Miners' Inches; Tables and Calculations; Flow of Water through Short Tubes and Compound Tubes; Flow of Water through Pipes; Tables of Velocities and Cubic Feet Flows for Given Fall per Mile and Diameter of Pipe; Coefficients for Round, Circular and Angular Flow through Nozzles; Inverted Siphons; Flow of Water in Open Channels; Extensive Tables; Rough and Ready Notes; Hints for Speedy and Approximate Estimates, etc.

Price, \$2.00, post-paid. Sold by Dewey & Co., Publishers, 252 Market St., San Francisco.

Books on Working Ores.

By GUIDO KUSTEL, M. E.

CONCENTRATION OF ORES (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams.

This work is unequalled by any other published embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in single order. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. Now out of Print. Very rare. A few orders only can be filled at \$10 per copy. Sold by Dewey & Co., Publishers, 252 Market St., San Francisco, Cal.

ROASTING OF GOLD AND SILVER ORES (Second Edition and the Extraction of their Respective Metals without Quicksilver. By GUIDO KUSTEL, M. E. 1880.

This rare book on the treatment of gold and silver ore without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and the why and wherefore. It contains 156 pages, embracing illustrations of furnaces, supplements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. Price, \$3, coin, postage free. Sold by Dewey & Co., Publishers, 252 Market St., San Francisco, Cal.

By C. H. AARON.

AARON'S LEACHING GOLD AND SILVER ORES, the most complete hand-book on the subject extant; 164 pages octavo. Illustrated by 12 lithographic engravings and four wood cuts. Fully indexed. Plainly written for practical men. In cloth, \$3. Sold by Dewey & Co., S. F.

Books on Assaying.

By C. H. AARON.

PART I.—Gold and Silver Ores.—Price \$1.

This new work is written by an experienced metallurgist who has devoted many years to assaying and working precious ores on the Pacific side of the American Continent. He writes what he knows from personal practice, and in such plain and comprehensive terms that neither the scientist or the practical miner can mistake his meaning.

The volume embraces 106 12mo. pages, with illustrations, well bound in cloth, 1884. Price, \$1, postpaid. Sold by DEWEY & CO., Publishers, No. 252 Market street, San Francisco.

PARTS II AND III.

Lead, Copper, Tin, Mercury, etc. Price \$1.75.

This book is entitled "Assaying—Parts II and III," and is separate from Part I, and treats of Gold and Silver Bullion, Lead, Copper, Tin, Mercury, Zinc, Nickel, Cobalt, etc.

There are 160 12mo. pages with illustrations in the volume, which is bound strongly in cloth. Price postpaid, \$1.75. Sold by Dewey & Co., Publishers, No. 252 Market St., S. F.

Testing and Working Silver Ores

An illustrated work of 114 pages, for miners and prospectors, by Chas. H. Aaron. Mr. Aaron has managed to give many useful hints and suggestions, free from all technicalities, and in such a style as to be easily comprehended. It is written for the miner, with no chemical symbols or metallurgical technicalities to confuse those who are not chemists or metallurgists. The following summary of the contents of the work will give an idea of its scope.

Under the heading of the first chapter, "Testing Ores for Silver," we find paragraphs on ore formation, test for silver, with heat and water, acid or blow pipe. In speaking of testing for a process, the extent and richness of ore is considered, smelting ores, selecting and working samples, appliances for testing, roasting, etc. Under the heading of "Working Ores" the author describes Aaron's process, has something to say of superheated steam, preparation of dichloride of copper and protochloride of copper, use of copper and iron, quantity of chemicals, carbonate of lime, chloride ore, amalgam, Patchen's process, etc. He also describes the methods of working roasted ores, treatment of base metals, stirring, heat of furnace, want of sulphur, etc. Under the heading of "Leaching Processes" are the titles Smelting, Mexican process, Chilean process, Kroehnke's process, etc. Under "Pulverizing Machines" are described the arastra and its construction and operation, stamp batteries, screens, Crocker's trip-hammer battery, Paul's pulverizing barrel, Kendall's battery, Noice's pulverizer, a cheap rock breaker, etc.

Speaking of amalgamators the author describes a

A \$65 FIRST-CLASS SEWING MACHINE AND THIS PAPER FOR \$23.

Premium No. 1.

The regular retail price of this Machine is \$65. Our price with a Year's Subscription for this paper is only \$23 in advance.

How to Order:

When you remit us the \$23 for the Machine and this paper, one year, write plainly the point the Machine is to be shipped to, as well as the Postoffice the paper is to

Order by freight unless you are quite beforehand to pay the cost by express.

This cut shows our HIGH-ARM No. 1 PREMIUM MACHINE, the very latest improved machine of the modern high-arm style; a splendid embodiment of the most recent improvements in sewing machine mechanism; a model well selected after a careful and critical examination and test of the various machines in the market.

Having arranged with the manufacturers to supply us with these machines in large quantities for spot cash at or very near first cost, we can save our subscribers about \$35 on the price of each machine.

OUTFIT.—Each Machine is supplied with the following outfit: One Hemmer and Feller (one piece), Twelve Needles Six Bobbins, One Wrench, One Quilting Gauge, One Screw-Driver, Oil Can filled with Oil, Cloth Gauge and Thumb-Screw, and a Book of Directions. The following extra attachments are also furnished free: Ruffler, Tuckor, Binder, Set of Wide Hemmers and Shirring Plate.

point on the Pacific Coast. We presume, however, the cost from Chicago to subscribers' residences will not cost, on an average, over \$5 each.

IMPORTANT.—No agent is authorized to receive payment for sewing machines under this offer, but parties laying in advance for this paper, through agents, can forward the balance for either premium with the order, and obtain the machine desired. The machine will be furnished by us to subscribers only.

Improved \$60 Standard Sewing Machine and this Paper for \$19.

Premium No. 2.

an excellent, durable, and desirable family machine. Samples of Premium No. 1 and No. 2 can be seen and operated in our office.

No. 2 Premium machine is well made and handsomely finished. Those who have had a Singer machine will know all about running this one, as it is simply a Singer machine, lock-stitch, tension and all, with some improvements on the Singer.

ready for use. The money, \$19, must accompany order. Address THE PUBLISHERS OF THIS JOURNAL, 252 Market St., S. F.

For any further information which any person may wish concerning Premiums Nos. 1 or 2, please write direct to our office.

IMPORTANT.—No agent is authorized to receive payment for sewing machines under this offer, but parties paying in advance for this paper, through agents, can forward the balance for either premium with this order, and obtain the machine desired. The machine will be forwarded by us to subscribers only.

The furniture is of the nicest finish. Each machine has a box cover, a drop-leaf table and five drawers; also a full set of the latest approved attachments and necessary instruments, viz.: One Foot Ruffler, one set Hemmers, one Tuckor, one Foot Hemmer or Feller, one packer, Needles, six Bobbins, Screw Driver, Oil Can, extra Check Spring, extra Throat Plate, Gauge Screw, Wrench, Instructions.

The fact that the best and most important features of sewing machine patents have run out, enables us, by the handling of an exceedingly large number of machines, through premiums to our subscribers, to furnish them at a great deal better advantage to the purchaser than they could be furnished where they are sold in smaller numbers annually, as is the case with retailers generally.

In Ordering.

Do not fail to write plainly your name and the address to which you wish the paper sent, and particularly and fully the R. R. depot, or freight point, to which the machine should be forwarded. The freight will be paid by the subscriber on arrival of the machine.

We would advise subscribers to order Machine sent by freight, as the freight charges are about one-third to one-fourth of express charges, and while the time taken in the carrying of the Machine is a little longer, they go just as securely and safely as by express. The Machines will be shipped direct from the manufacturers (Chicago), all set up

Practical Treatise on Hydraulic Mining

By AUG. J. BOWIE, JR.

cheap amalgamator, grinding the ore, directions for making a barrel, preventing mechanical wear; use of quicksilver; copper in bars, Freiberg barrel, cheap barrel trough, barrel on rollers, Aaron's amalgamator, separator, etc.

He describes an improvised retort, roasting furnace, furnace tongs and furnace building. Among the miscellaneous mention may be found Aaron's leaching apparatus, with two or three different arrangements, a small mill, sampling tailings, and settling tanks, dichloride of copper, etc. Mr. Aaron is a practical miner, of long working experience on this coast.

Price, post free, \$2.00. Sold by Dewey & Co., Publishers, 252 Market St.

This new and important book is on the use and construction of Ditches, Flumes, Dams, Pipes, Flow of Water on Heavy Grades, methods of mining shallow and deep placers, history and development of mines, records of gold washing, mechanical appliances, such as nozzles, hurdy-gurdies, rockers, undercurrents, etc.; also describes methods of blasting; tunnels and sluices; tailings and dump; duty of miners' inch, etc. A very practical work for gold miners and users of water. Price, \$5, post-paid. For sale by Dewey & Co., Publishers, 252 Market St., San Francisco.

NOTICE TO MINING MEN, ENGINEERS, CONTRACTORS, and others interested in TUNNELING, SHAFT-SINKING, ETC. Engineers' Tables of Progress

WITH MAPS, ILLUSTRATIONS AND FULL DESCRIPTION OF THE

NEW YORK AQUEDUCT TUNNEL

Section 16x16 feet; Length 36 miles.

About Obtaining Patents.

Patents are Virtually Contracts

Between inventors and the public. The consideration flowing from both parties to the contract is expressly fixed by statute. The Government requires the following considerations in every case: First, that an applicant for a patent shall disclose a new and useful improvement, of which he is the first and original inventor. Second, that the invention has not been patented, or published in a printed publication prior to the date of his invention. Third, that the invention has not been in public use, or on sale, more than two years prior to his application for a patent. Fourth, that the invention shall be properly described and claimed in the specification forming a part of the patent. Provided an inventor complies strictly with these conditions, the Government guarantees that the inventor shall have the exclusive right to make, use and sell the thing invented for the term of seventeen years.

The Patent Law provides that in case a patent, which is the evidence of the contract, is not executed in compliance with the requirements of the law, it may be annulled and rendered void. Hence, it is of the greatest importance to every inventor that his patent or contract be skillfully and accurately drafted, that it may afford him complete protection for his invention during the life of his patent.

Secure a Good Patent.

An inventor should first ascertain whether or not his improvement has been patented to another. This requires an exhaustive search among all the patents in the class to which the invention relates. This question can often be answered gratuitously by us, immediately on receiving full information of the invention, by reason of our long and extensive practice as patent solicitors and editors and publishers of first-class, scientific and industrial journals, during the past 20 years and over. When the question of priority of invention is not so readily to be determined, it is generally best to make what is termed a "preliminary examination," by searching through the patent office reports among the patents in the class to which the invention relates, and referring to our extensive patent library, containing compilations of special classes of American and foreign inventions, mechanical dictionaries, scientific encyclopedias, files of scientific and mechanical newspapers, and an immense number of patent applications by inventors of the Pacific coast, carefully filed by this office since 1860.

If, by this "preliminary examination," the improvement is found to have been previously invented, our client will receive, for the small sum of \$5 for the examination, a verbal or written report showing definitely whereby his invention has been anticipated, thereby saving him further expense and perhaps much time, useless delay, anxiety, etc.

To avoid all unnecessary delay, however, in securing patents at the earliest moment practicable, inventors will do well to forward a model, drawing or sketch, with a plain, full and comprehensive description of their invention (stating distinctly what the particular points of improvement are), with \$15 as a first installment of fees. If the improvement appears to us to be novel and patentable, the necessary papers for an application for a patent will be prepared immediately, and forwarded to the inventor for his signature. When the inventor receives the application and finds it duly prepared, he will carefully sign and return the same plainly addressed to us, with postal money order or express receipt for our own fee. The case will then be promptly filed by us in the Patent Office, and vigorously prosecuted to secure the best patent possible. [This course is the most expeditious and satisfactory, as no time is lost in transmitting correspondence relative to the preliminary steps to be taken.] When the patent is allowed the inventor will be duly notified, and on sending the final Government fee of \$30 to us, we will order the issue of the patent, and forward the same as soon as it is secured from the Patent Office.

The payments are thus divided and made easy. We make no pretense of doing cheap work, in order to entice custom, nor do we afterward make additional charges to bring the bill up to a fair compensation. We do our work honestly and thoroughly, and we never give a case up as long as there is a chance to obtain a patent. The agency charge is from \$25 to \$30, or sometimes more, if the invention is intricate or complicated, or requires much labor. Drawings cost from \$5 upward, according to their number and the time employed, and, if a model is sent, the express charges upon this and the papers must be added. The total cost, in addition to Government fees, rarely exceeds \$40, and for this we do all we can without appealing the case.

When the invention consists of a new article of manufacture, or a new composition, samples of the separate ingredients sufficient to make the experiment, and also of the manufactured article itself, must be furnished.

Models and Drawings.

Models are now seldom required by the Commissioner of Patents, and generally only in intricate cases. Perfect drawings of practical working machines are considered more satisfactory to the Patent Office than the old and more cumbersome system of storing up an immense bulk of almost numberless models.

Drawings or sketches, sufficient to illustrate clearly the invention, with a sufficient description to enable us to make a full set of perfect drawings for the Patent Office is all that we require. A model will answer our purpose as well however, in cases where the inventor can more easily furnish it for our use.

The value and even the validity of a patent often depends on the character, clearness and sufficiency of its drawings. There are thousands of existing patents in which the improvements are but partially or very poorly illustrated in the drawings. When an attempt is made to dispose of such patents, the vagueness and defects of the drawings often prejudice capitalists and manufacturers against the invention while in reality it may be of great value, and would meet with ready sale had the invention been fully portrayed by artistic and skillfully executed drawings. Again, when patents of this character are brought into court, the uncertainty and ambiguity of the drawings enable the opposing experts to mystify the judges as to the construction or combination of parts intended to be covered by the patentee. In all cases prepared by us, the drawings are made under our personal supervision, by skilled draftsmen in our constant employ, and every precaution is taken that the invention is fully and clearly shown by different views, so that the improvement will be readily understood by the Examiners in the Patent Office, and comprehended by the public when the patent is granted.

In the Patent Office

The application is assigned to the Examiner having charge of the class to which the invention relates. The case must then take its turn with others in the order of filing, and in due time is carefully examined to test the novelty of the in-

vention. If the examiner fails to find anything that anticipates the invention, a patent is immediately allowed, provided the specifications and claims are drafted in proper form. Should the Examiner find a prior patent which, in his opinion, anticipates one or more of the claims in the application, a letter of rejection is sent to the attorney in charge of the case; and, if the attorney coincides with the views of the Examiner, the claims rejected are erased. In preparing applications for patents, an attorney should be careful to familiarize himself with the class of inventions to which the application pertains, so that the specification and claims may be drafted as nearly perfect in the first instance as is possible. This course saves much time in prosecuting the application to a patent.

When claims are improperly rejected on patents which do not anticipate the spirit or wording of the claims, proper steps are immediately taken to convince the Examiner of his error. This is done, in most part, by personal arguments, as the differences in construction, operation, function and results are more readily discovered and appreciated by an oral presentation of the facts than can possibly be done by relying solely on written arguments. In order that the Patent Office record of the patent be complete, an oral argument is generally supplemented by a manuscript brief, that others, in examining the files at any future time may clearly comprehend the position taken by the Examiner and attorney in prosecuting the case to a patent.

In addition to our own personal attention to the interest of our clients here, we have, for over 12 years past, had constantly in association with us in Washington, one of the soundest legal counselors and ablest of practitioners in patent business in this country, who carefully attends in person to our business at the Patent Office, and has attained success in a most marked degree.

Perfect Claims.

The value and force of a patent are dependent on its claims. A patent may disclose to the public the most important and valuable invention, and yet the claim be of such meager scope that the patent is actually worthless. When the claims of a patent are so loosely drafted that infringers can flood the market with improvements, differing from the improvement disclosed by the patent only in slight changes in construction and arrangements of parts, such a patent is valueless to the owner, as it fails to afford him that exclusive and complete protection guaranteed by the Patent Law. Hence it is that the greatest care, skill and perseverance are required, first, in properly drafting the claims in the first instance, and second, in prosecuting the application before the Patent Office, and maintaining the rights of the inventor to claims as broad and sweeping as the invention will warrant. This latter is no easy task. The Examiners of the Patent Office serve in the capacity of attorneys guarding the interests of the public. It is their sworn duty to exercise the greatest care and watchfulness, that patentees do not secure claims of greater scope than they are justly entitled to. It is but natural that Examiners are sometimes in error as to just what scope should be accorded an invention. Although the Examiners act under honest convictions in cases where they refuse an inventor his just rights, yet it is the duty of the attorney to maintain the claims of his client, if he is convinced that they are just and proper. To succeed in this requires the display of tact, firmness and ability; and when the Examiner is made to see that the inventor is honestly and fairly entitled to the claims which have been rejected, he will almost invariably recede from his former action, and allow the case.

Advantages to Inventors on the Pacific Coast.

The firm of DEWEY & Co. (continuously editors and publishers of the MINING AND SCIENTIFIC PRESS, nearly from its early commencement in 1860) offer comparatively far better facilities to the local inventors of the Pacific States and Territories than are possessed by any other agents in America. Members of the firm give personal attention to the applications entrusted to their care. They have been longer in practice in patent soliciting than most agents who are still personally engaged in the business. They have secured more U. S. and foreign patents in the past 20 years (with very few exceptions) than any other firm still existing. Their practice has been so successful and long continued, that the great majority of inventions on this side of the American continent have been patented through their agency, thus affording them great and valuable experience, by thorough information of the true principles and points of novelty in the inventions, whether general in character or peculiarly local to this coast.

The extensive business combination and experience of this firm is undoubtedly one of the most fortunate in existence for affording inventors prompt and reliable advice, and the best possible facilities for securing their full patent rights with safety and dispatch at uniformly reasonable rates.

Every patentee of a worthy invention is guaranteed the gratuitous publication of a clearly-stated and correct description of his invention, in one or more of our influential and reliable newspapers, affording just the circulation that is best calculated to widely inform the class of readers most specially interested in the subject of his invention.

Saving of Time, Etc.

Inventors on this coast will find that owing to our familiarity with inventions and local affairs of this coast, we can more readily and fully comprehend their wants, and thus save much of the time ordinarily consumed in preliminary writing back and forth when distant agencies are employed.

Caveats.

A caveat is a confidential communication made to the Patent Office, and is therefore filed within its secret archives. The privilege secured under a caveat is that it entitles the caveator to receive notice, for a period of one year, of any application for a patent subsequently filed, and which is adjudged to be novel, and is likely to interfere with the invention described in the caveat, and the caveator is then required to complete his application for a patent within three months from the date of said notice. Caveat papers should be very carefully prepared. Our fee for the service varies from \$10 to \$20. The Government fee is \$10 additional.

To enable us to prepare caveat papers, we only require a sketch and description of the invention.

Rejected Applications.

Inventors who have rejected cases (prepared either by themselves, or for them by other agents), who desire to ascertain their prospects of success by further efforts, are invited to avail themselves of our unrivaled facilities for securing favorable results. We have been successful in securing Letters Patent in many previously abandoned cases. Our terms are always reasonable.

Inventors who do business with us will be notified of the state of their application in the Patent Office, when it is possible for us to do so.

THE FRISBEE-LUCOP MILL,

A CENTRIFUGAL ROLLER MILL

—FOR—

Reducing Ore, Quartz, Phosphate Rock, Carbon, any other Mineral Substance to any degree of fineness in a rapid and economical manner.

At 300 revolutions per minute will pulverize 2000 pounds of quartz per hour to 60 mesh dry, and from 3000 to 6000 pounds wet.

All wearing parts easily and cheaply replaced. May be seen in operation at the New York Metallurgical Works, 104 and 106 Washington Street.

Certificates as to performance of the Mills, and any information required, furnished on application.

THE FRISBEE-LUCOP MILL CO.,

Office, 104 & 106 Washington St., NEW YORK.

ÆTNA HOT MINERAL SPRINGS.

Nearly identical with the Celebrated Ems of Germany.

For Rheumatism, Neuralgia, Paralysis, Liver and Kidney Complaints, Dyspepsia, Malaria and General Debility, these waters prove highly curative. Situated at the head of Pope Valley, 1400 feet above sea-level. No malaria; no mosquitoes. A fine swimming bath attached. Camping grounds free. Stage leaves St. Helena daily (Sundays excepted) on arrival of A. M. train from San Francisco. For circulars of cures performed and analysis of the waters, address W. H. LIDELL, Prop'r, or S. J. STEUART, Supt., LIDELL, NAPA CO., CAL.

REFERENCE IN SAN FRANCISCO—EX-MAYOR A. J. BRYANT, ALVINZA HAYWARD, Prof. W. T. WENZEL, Ex-Lieut. Gov. Maclean, D. O. Mills, Dr. G. B. Crane, Rev. Dr. Coyle, Dr. R. H. Plummer, Thomas Agnew, Capt. T. H. Barber, Prof. A. J. Bacon.

PATENT LIFE-AVING RESPIRATOR

Entirely Prevents Lead Poisoning and Salivation

The most perfect appliance for people engaged in Smelting, Dry Crushing, Guano Works, Quicksilver Mines, Lead Corroding, and all other occupations where there is dust, poisonous vapor, or bad odor.

In Feeding Threshing Machines, and similar work, they are indispensable, as no foreign substances can be inhaled when they are worn.

The Respirators are sold subject to approval after trial, and if not satisfactory the price will be refunded. Price, \$3.00 each or \$30.00 per dozen. Sent post-paid to any address on receipt of price.

Address communications and orders to

T. E. JEWELL, Sole Agent,

THE PEOPLE'S CYCLOPEDIA

Is the Best in the World for General Use.

NEW THREE-VOLUME EDITION NOW READY.

Comprehensive and compact—53,000 topics. Complete in three convenient volumes. Reliable—400 first-class contributors.

Fresh—Brought down to the present year.

Now Ready.—Subscribers not kept waiting with only part of a cyclopedia.

Really Cheap.—Less than half the price of similar works.

It answers fifty-eight thousand questions, some of which are constantly asking themselves in the minds of all who think. It ought to be in every family, school and business office.

OVER 75,000 SETS ALREADY SOLD.

Send to us for specimen pages, etc., that you may see for yourself. For terms, etc., address

PHILLIPS & HUNT,

25 to 31 MAIN STREET, SAN FRANCISCO, CAL.

91 to 93 FRONT STREET, PORTLAND, OR.

SOLE AGENTS FOR

GARDNER GOVERNOR COMPANY,

J. S. Mundy's Patent Friction Hoisting Engines.

The Mundy Patent has been sustained in the United States District Court of New York against the Ledgerwood Manufacturing Company, and also in the District Court in the State of New Jersey against Kendall & Roberts for infringement. Therefore all parties are cautioned against making, using, or selling Friction Drums that infringe this patent.

Gardner Governor.

GORDON & MAXWELL COMPY MINING PUMPS.

THE MOST EXTENSIVE PUMPING MACHINE WORKS IN THE UNITED STATES.

MORRIS COUNTY MACHINE and IRON CO. New High-Speed AIR COMPRESSOR.

We have recently furnished the contractors the machinery for La Trinidad (300 tons per day) and Silver Queen (100 tons per day). These mines are located in Mexico and belong to La Trinidad Company, of London. The Process is the Wet Concentration, and the Plants are, without doubt, the most substantial and complete of the kind ever built.

WE MANUFACTURE ENGINES, BOILERS, AND SAW-MILL MACHINERY, and Carry in Stock:

Wood and Iron Working Machinery, Best Belting, Lubricants for Cylinders and General Machinery Including the Celebrated ALBANY LUBRICATING COMPOUND.

SEND FOR CIRCULAR.

IMPORTANT TO GOLD MINERS! SILVER-PLATED AMALGAMATING PLATES FOR SAVING GOLD

IN QUARTZ, GRAVEL AND PLACER MINING.

Warranted the Best Made, Durable and Satisfactory. Full weight of silver and best quality of plating guaranteed.

BEST SOFT LAKE SUPERIOR COPPER USED.

3000 Orders filled. References first class. Prices the very lowest. Have received every Medal awarded on the Pacific Coast for Mining Plates. Old Mining Plates Bought, Replated, or Gold Separated.

SAN FRANCISCO GOLD, SILVER and NICKEL PLATING WORKS, 653 & 655 Mission St., San Francisco.

E. G. DENNISTON, Proprietor.

These Plates can also be procured of JOHN TAYLOR & CO., Dealers in Assayers' and Mining Material, 112 to 118 Pine St.

NOTICE.—Mining men are cautioned against purchasing inferior quality of Silver-Plated Mining Plates now being manufactured in this city. There has been a general complaint by purchasers that these plates proved defective in plating and short in weight of silver, assays showing great deficiency in silver guaranteed. Thin, light plating LOOKS the same as heavy, but has no durability. Good plates can be furnished at same price these poor plates cost.

Working Gold-Bearing Sulphurets.

Concentration and Chlorination in Nevada County, Cal.—No. 4.

[Written for the Press by C. A. SCHENCK.]

The Furnaces.

The roasting is performed in two elliptical furnaces, having one chimney in common, divided by a partition. Each one has three floors or hearths, one above the other. The upper or third floor is not covered by an arch, and is only used to finish the drying before the ore is introduced to the middle hearth, where the roasting process begins. There is room for about five tons on this upper floor, so that the layer is from four to five inches thick. By means of two drop-holes in the arch of the middle hearth, the ore is conveyed to the floor of the latter. This hearth is provided with three working doors—ones at the end of the long axis of the ellipse, the other two near the opposite end, so that the chimney stands between them. From the middle hearth one drop-hole only leads to the lowest one, which is provided with four working doors; the fire-place is on the chimney side of this lower hearth, and occupies part of the elliptical area of this floor. Four holes, through which the roasted ore is dropped, lead from this floor into arched ways in the lower masonry of the furnace.

A distinguishing feature of this roasting furnace is the solid iron binding, besides its elliptical form and the three-hearth system. A charge of roasted ore, about two and one-half tons, is drawn every 12 hours—one at 2 P. M., the other at 2 A. M., whereupon one-half of the ore on the middle hearth is dropped on the floor beneath, which has been made ready for its reception by the previous discharge. The drop-hole from the middle floor being near the one work-door end, the workman works now from this side, till one-half has been transferred to the lower hearth; then he goes around to the second work door end of the middle hearth, and pushes the remaining one-half with his hoe over to the opposite side, having previously closed the drop-hole. By this operation he has made room for two and one-half tons of dried ore from the uppermost hearth, which, in coming down, forms two dark-looking conical piles, which he spreads out in an even layer on the empty floor, between short axis and two work-door ends. Then he goes down to the lowest hearth to spread out the pile on this floor. During all this time some of the work doors have been by necessity left open and he has to fire up, whereupon the ore on the lowest hearth soon gets red hot, and the sulphur of the ore on the middle floor begins to burn with the characteristic blue flame.

During the meantime another workman has transferred to the drying floor as much ore as was dropped to the middle hearth.

Working the Charge.

It can be easily seen from this description that the ore on the middle hearth is in two different stages of roasting; the first half of the charge near the one work-door end being 12 hours ahead of the other half, so that the first-mentioned portion of ore, when it is advanced far enough to be soon discharged to the lowest hearth, shows only very few sparks and almost no burning sulphur, when it is worked with the hoe; it is also less woolly in appearance than the other portion on the same middle floor, which is 12 hours behind, and does not run so much from the hoe as if it was wetter, when the hoe is passed through it, which the other less advanced portion shows in such a remarkable manner, showing besides pale blue flames of burning sulphur and sparks in profusion.

At about 4 A. M. (and 4 P. M.) salt (from one-half per cent) is charged to the red hot ore on the lowest floor and diligently worked into it with the hoe. White vapors arise in profusion and the sky-blue flame of the chloride of copper is also noticed off and on. If at last the salt is well worked into the ore the latter is piled up in one heap, which extends from the flue to the bridge, in which state it is left a couple of hours and then spread out again over the whole hearth to be raked from time to time (about every 15 minutes) till 12:30 P. M. and 12:30 A. M. respectively, when it is banked up in four piles to be discharged at 2 P. M. (2 A. M.). The discharged ore forms a conical pile on the floor, and is allowed to cool off before further handling, during which time the process of chlorination

continues. This temperature on the lower hearth is not allowed to sink much below red heat; sometimes it rises to light red; whereas on the middle hearth it is quite different, on which a slow increase of the temperature is most advantageous. Besides from the heated gases from the lower floor, heat is derived here from the burning sulphur; but this latter source decreases continually as the ore advances in roasting, so that it happens that the more advanced charge on this floor looks almost dark on its surface, while a charge, which in time is 12 hours behind, is dark red and shows pale blue flames of burning sulphur.

The furnace is provided with the usual means for regulating the heat; it consumes about 1½ cords of wood in 24 hours.

The lower hearth surface is about five-sixths of the area of the middle and upper floors, the other one-sixth, being occupied by fire-place and bridges. For this reason, and also on account of the ore receiving here the finishing roast, which latter circumstance permits only the handling of smaller quantities, the lower hearth can only be charged with about half the ore on the middle and upper hearths. This explains at the same time the fact that one-half of the ore on middle floor is 12 hours ahead of the other half. In practice it has been found of advantage to leave a space free of ore, which extends from the fire-bridge about one foot into the furnace.

Well-roasted ore is of a dull grayish-blue color. It should not feel gritty to the touch, but soft like flour (making allowance for the sand mixed with it). The workman uses the following test to satisfy himself about his work: A shovelful of the roasted ore, shortly after discharge, is spread out in a thin layer on the brick floor; if it burns gradually into reddish-brown he considers the ore well roasted.

A Reverberatory.

Besides the three-hearth elliptical furnace of the Providence M. & M. Co., another one of different construction is extensively used in the district—a reverberatory which is from 60 to 70 feet long and divided by a step into two floors, so that the upper floor lies in the extension of the lower, only 12 inches higher. The dimensions of the lower hearth are 17 feet from fire-bridge to the flue which leads to upper hearth, and 10 feet across. It has no auxiliary fire-place for the upper hearth, which, considering its length, a great many might think would be needed. During the long passage of the concentrates from upper end down to the fireplace, the roasting is very gradually done, so that the work in this furnace is considered to be very satisfactory. About three tons of roasted ore are obtained in 24 hours, consuming one cord of wood in this time. It needs two workmen at a time to run this furnace, whereas one man can do all the work around an elliptical furnace.

New Pulverizing Mill.

Robert Forbes, of Downville, Sierra county, has just obtained through the MINING AND SCIENTIFIC PRESS Patent Agency a patent for an improved pulverizing mill of that class in which an eccentrically moving or "wabbling" muller operates in an annular space in a pan or vessel and around a central guiding core.

The pan or vessel has sloping sides and a central conical core by which is formed an annular or ring-shaped space, on which are seated the removable dies. Sectional screens are secured to and continue the inclination of the pan. On the rim of the pan is an exterior flange under which is an annular discharge trough set on an angle.

The muller is made of an annular shape and provided with shoss. The muller is received by a spider to a shaft, the upper end of which is eccentrically connected with a crank-shaft whereby the muller has imparted to it a wabbling or eccentric motion within the pan and around the central core. The muller is provided with a hopper, and over the edge of this, and fitting snugly upon or within the top of the screen, is an annular shield. This shield is made preferably in the shape of a truncated cone, its central opening being somewhat smaller than the diameter of the upper portion of the hopper, whereby all liability of the ore between the screens and the muller is avoided.

Around the central core is an annular shoe, which may be readily put in place or removed. On the inner surfaces of the muller-shoss are

wearing blocks which are adapted to be renewed when necessary. The screen sections are secured to the pan in a peculiar and effective manner.

The operation of the machine is as follows: The annular muller fits down into the annular space of the pan, and the material to be crushed is fed into the hopper of said muller and passes down through it, finally working its way between the shoes and dies. The shield, by extending over the hopper, prevents any material from getting down between the periphery of the muller and the screen-sections. The muller is given a "wabbling" motion and is guided in this motion about the central core of the pan.

As considerable wear occurs between the inner surface of the muller and the central core, it is necessary to provide the latter with a shoe of some kind. This has been done heretofore by independent blocks, which are separated from each other and serve also to center the muller. Mr. Forbes has found that in using said blocks the material is apt to get between them in rather large pieces which are not crushed. He has, therefore, discarded the blocks and uses a continuous-ring shoe, such as described, which effectively protects the central core, guides the muller as well, and acts as a perfect crushing surface. The wearing blocks on the inner surfaces of the muller shoes provide for the wear on this portion of the muller, which takes place between the shoes and the central core.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific States.

From the official report of U. S. Patents in Dewey & Co.'s Patent Office Library, 262 Market St., S. F.

FOR WEEK ENDING MAY 25, 1886.

342,418.—BUTTON HOLE ATTACHMENT FOR SEWING MACHINES—E. O. Bennett, S. F.
342,566.—TRACK CLEARER—L. J. Bergendahl, Pendleton, Ogn.
342,572.—PROPELLER FOR VESSELS—W. L. Boyer, S. F.
342,596.—PULVERIZING MILL—Robt. Forbes, Downville, Cal.
342,435.—ORE CONCENTRATOR—W. A. Frank, Final, A. T.
342,393.—FIREARM—Thos. Kelly, S. F.
342,616.—RAIN WATER FILTER—B. Leggett, Tucson, A. T.
342,453.—CULTIVATOR—Neil McLean, Watsonville, Cal.
342,467.—VELOCIPEDE—C. T. Ryland, jr., San Jose, Cal.
342,644.—GRAIN SOWER—W. Sharkey, Oroville, Cal.
342,768.—PADDLE WHEEL BUCKET—Trullinger & Scott, Astoria, Ogn.
13,335.—TRADE MARK—Knappion Packing Co., Oakland, Cal.

NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

VALVE GEAR.—John B. Pitchford, assignor of one-half to Wm. T. Garratt, S. F. No. 342,835. This invention relates to certain improvements in the means for actuating the valve gear of engines. It consists in a novel manner of constructing cams, and in their application for the working of the valves of steam engines, so as to cut off the steam either at a fixed point in the stroke or at one which is automatically variable.

CAR COUPLING.—Frank Miller, Olema, assignor of one-fourth to U. M. Gordon, San Rafael, Marin county. No. 342,028. Dated May 18, 1886. This car coupling consists in oppositely located spring-actuated drawheads of peculiar construction, a novel pivoted or swinging hook in each drawhead, a spring-actuated lock-bar for each hook, and means for withdrawing the lock-bar. This car coupling is automatic, and the release can be effected without going between the cars.

CULTIVATOR.—Neil McLean, Watsonville. No. 342,453. Dated May 25, 1886. This cultivator is one which is especially adapted for orchard use. It consists of a frame comprised of two or more parallel timbers, having teeth fixed to it, so as to present their points transversely to one side of the frame, an open based triangular frame attached to one end, with the apex toward one side and anti-friction rollers set within it, wheels mounted upon a cranked axle extending centrally across the frame, and a means for raising and lowering the frame about these wheels, a hinged swinging wheel attached to the front end of the frame, with

means for attaching a team thereto. The device is specially intended for cultivating the ground in orchards and around trees in which the branches hang low and extend outward so far that it would be impossible to cultivate close to the trees, by reason of the side draft of a cultivator constructed with an extension to one side for that purpose.

IRONING MACHINE.—Constant Wolff, S. F. No. 341,980. This relates to the class of machines for ironing small articles of clothing, more especially collars and cuffs. A cors is first heated and is then placed in an iron having a flat surface, and the lid is closed. The article to be ironed is placed between the roller and the flat bottom of the iron, and a treadle is pressed so the iron and the roller are brought together with the requisite degree of pressure on the article. The crank of the roller-shaft now being turned, the article is fed through under the iron.

PISTON ROD AND VALVE STEM PACKING.—Charles Wetson, S. F. No. 341,973. Dated May 18, 1886. This is an improvement in packing for piston-rods and steam-valve stems or other rods which reciprocate through a joint which will be exposed to steam or vapor under pressure. It consists of a set of spring-actuated packing-rings fitted at either end of the stuffing-box gland and in combination therewith; of an intermediate ring of greater width fitted to the rod, and in certain details of construction.

ENGINE VALVE GEAR.—John B. Pitchford, assignor of one-half to Wm. T. Garratt, S. F. No. 342,036. Dated May 16, 1886. This invention relates to a mechanism for operating steam valves, and more particularly to the non-detaching cut-off valve gear applied to engines of the Corliss type. It consists of an equalizing lever suspended and swinging from a point near the middle upon a pin on the arm that imparts motion to the rotary or Corliss valve, in combination with an intervening mechanism, consisting of an arm, hall-crank or disk, and a swinging link or lever connected to an eccentric controlled by a governor.

VELOCIPEDE.—Claus T. Ryland, Jr., San Jose. No. 342,467. Dated May 25, 1886. It consists of a single large wheel having a seat and operating mechanism supported from the axle within the wheel, two smaller tillers or steering wheels with a connecting frame by which they are supported just outside the rim of the main wheel, a ratchet mechanism for driving the main wheel, and pedals connected therewith, a hollow shaft with rods by which the back and steering mechanism may be operated and jointed spokes in the main wheel which may be separated for the ingress or egress of the rider.

Mining Share Market.

Mining stocks continue dull. The sinking of the combination shaft deeper has been the principal feature in the deep developments of the Comstock during the week. About 24 feet per week is the regular rate of sinking progress. The shaft has reached the 3200 level. This certainly is an important era point in the mining history of the world. This shaft is now 3200 feet in perpendicular depth from the collar or surface of the shaft to the bottom, perfectly straight, so that a stone dropped from the center of the shaft at the surface would strike the center of the bottom. Mining has been carried to a very little greater depth in the world, or even on the Comstock, but, as before remarked, the Combination shaft is to-day the deepest perpendicular or vertical shaft anywhere in the world. It will be continued 60 feet deeper for a sump or drainage well for the pumps to operate from, and further sinking probably discontinued until the present lowest levels are thoroughly explored.

As soon as practicable a station will be opened at the 3200 level, and a lateral drift started north to connect with the drift now coming south from the Hale and Norcross deep winze, 3200 level. The bottom of this shaft having cut into the main Comstock ore channel, as was expected, owing to the regular dip of the vein, about 45 degrees to the east, all deeper sinking of the shaft will be all the same as crosscutting the ledge toward the west or foot wall; but when the station is opened on the 3200 level it will be on the west side of the shaft, and a drift or crosscut west is to be started from it directly through the vein to the west wall, the lateral drift to the Hale and Norcross deep winze being run at the same time. Some very effective and decisive prospecting explorations of the deepest Comstock workings at this point will be done during the next month or two, and work of very important interest in the future hopes of the great lode.

THE MINT.—The annual clean up at the Mint will commence on the 12th inst., and after that date no base hullion will be received. Refined bullion will be accepted until the 19th inst.

THE electric road through First street to the summit of Boyle Heights, Los Angeles, is an assured fact, the rails being on the way.

1850. 1885.
RANKIN, BRAYTON & CO.,
...BUILDERS OF...
MINING MACHINERY.

San Francisco: 127 First Street. Chicago: 100 N. Clinton. New York: 145 Broadway.

PLANTS FOR GOLD AND SILVER MILLS, embracing machinery of LATEST DESIGN and MOST IMPROVED construction. We offer our customers the BEST RESULTS OF 35 YEARS' EXPERIENCE in this SPECIAL LINE of work, and are PREPARED to furnish from SAN FRANCISCO or CHICAGO, the MOST APPROVED character of MINING AND REDUCTION MACHINERY, adapted to all grades of ores and SUPERIOR to that of any other make, at the LOWEST POSSIBLE PRICES.

We are also prepared to CONSTRUCT and DELIVER in COMPLETE RUNNING ORDER, in any locality, MILLS, CONCENTRATION WORKS, WATER JACKET SMELTING FURNACES, HOISTING WORKS, PUMPS, ETC., ETC., of any DESIRED CAPACITY.

WATER JACKET SMELTING FURNACES

For COPPER and ARGENTIFEROUS LEAD ores of NEW and ORIGINAL DESIGNS, covered by LETTERS PATENT. No other Furnace CAN COMPARE with these for DURABILITY, and in CAPACITY for uninterrupted work. MORE THAN 150 of them are now RUNNING in various parts of THIS COUNTRY, as well as many in FOREIGN COUNTRIES, giving results NEVER BEFORE ATTAINED as regards CONTINUOUS running, ECONOMY of fuel, AMOUNT and QUALITY of BULLION produced. These CLAIMS have been PROVEN BY RESULTS in ANY NUMBER of INSTANCES, and the GREAT SUPERIORITY of this SYSTEM of smelting ores DEMONSTRATED BEYOND QUESTION. COMPLETE PLANTS furnished to order of any CAPACITY, with ALL IMPROVEMENTS that experience has DEMONSTRATED as VALUABLE in this class of work.

Beyond question the cheapest and most effective machine of the kind now in use adapted to all grades and classes of ores.

This machine has been THOROUGHLY TESTED for the past TWO YEARS, under a GREAT VARIETY of CONDITIONS, giving most EXTRAORDINARY results FAR IN ADVANCE of anything EVER BEFORE REALIZED. A recent COMPETITIVE TEST at the Carlisle Mine in Mexico, showed an ADVANTAGE OF OVER 30 PER CENT in favor of THE DUNCAN. The amount SAVED OVER THE TRUE being sufficient to PAY THE ENTIRE COST of the machines EVERY MONTH of the YEAR. One of its MOST VALUABLE features is as an AMALGAMATOR. It saves all THE AMALGAM GOLD and SILVER that ESCAPES the BATTERIES, PANS or SETTLERS, making the machine worth MORE than ITS COST for THIS PURPOSE ALONE.

Baker's Mining Horse Power.

Possessing all the requirements of a first-class hoist and affording means for the continuous operation of a Pump or Blower, without interfering with a hoisting apparatus. It is made entirely of iron, no piece weighs over 800 pounds. At the ordinary speed of a horse, a 1,000-pound bucket of ore may be raised 120 feet per minute. The hoisting-drum is under the complete control of the man of the shaft, and is capable of carrying 600 feet of five-eighths steel rope. SEND FOR CIRCULAR.

CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding homastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 (XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

JOHN F. LOHSE, SEC'Y.

Office, No. 230 California Street - - San Francisco, Cal.

THE GIANT POWDER COMPANY

THE JENKINS STANDARD PACKING

IS ACKNOWLEDGED BY USERS AS THE BEST in the world. Unlike all other Packings, the Jenkins Standard Packing can be made any thickness desired in a joint by placing two or as many thicknesses together as desired, and following up joint, it vulcanizes in place and becomes a metal of itself (it is frequently called Jenkins Metal), and will last for years, as it does not rot or burn out. Avoid all imitations, as a good article is always subject to cheap imitations. The genuine has stamped on every sheet "Jenkins Standard Packing," and is for sale by the Trade generally.

Manufactured only by

CALIFORNIA ARTIFICIAL STONE PAVING CO.

(SCHILLINGER'S PATENT.)

—FOR—

**SIDEWALKS, GARDEN WALKS, CORRIDORS, OFFICES, CARRIAGE
DRIVES, STABLES and CELLAR FLOORS, KITCHENS, Etc.**

The Courts here and in the East have decided that Artificial Stone Pavements with plastic concrete and in detached blocks, are infringements on the Schillinger Patent; and also, that when the plastic material is blocked off with a trowel and cut through far enough to control the cracking caused by shrinkage, that such pavement is in law the same as if laid in detached blocks, and is an infringement of the patent. All property-owners having such pavements laid without the license of the above Company, will be prosecuted.

OFFICE, 404 MONTGOMERY STREET, SAN FRANCISCO.

ADAMANTINE.

We manufacture the above Adamantine Shoes, Dies and Crusher Plates. They are in use on the hardest quartz in the United States and South and Central America, and have been for the last ten years; we warrant them to out-wear three (3) sets made of any other metal, and many report that they last from 4 to 8 times longer than any other make. They never break AT THE SHANK, and the wear is so light that little or no foreign matter gets mixed with the crushed ore.

Also CHROME CAST STEEL for Mining and General Use, of the finest quality.

For further particulars, address

CHROME STEEL WORKS,

H. D. MORRIS, Agent, 22 Fremont St., San Francisco.

When ordering, a rough sketch, with full dimensions, is all that is necessary.

THE ROLLER ORE FEEDER

[Patented May 23, 1882.]

This is the best and cheapest Ore Feeder now in use. It has fewer parts, requires less power, is simpler in adjustment than any other. Feeds coarse ore or soft clay alike uniformly, under one or all the stamps in a battery as required.

In the Bunker Hill Mill it has run continuously for two years, never having been out of order or costing a dollar or repair.

Golden State and Miners' Iron Works.

Sole Manufacturers,

237 First Street, San Francisco, Cal.

THE Sign of the Arkansas Cough Syrup is looking you all square in the face.

Do you want a sure, safe and reliable Cough Syrup? Are you troubled with a Cough, Cold, Bronchitis or Lung Complaint? Do your Babies keep you awake all night with Hacking Coughs, Colds in the Head, etc. Do you want something reliable in the house to meet these emergencies? We answer to all: "Go to your Druggist and get a Bottle of the Arkansas Cough Syrup, and be troubled no more." Price, 50 cents per Bottle!

FOR SALE BY ALL DRUGGISTS.

THE ORIGINAL Roller Ore Feeder.

(PATENTED JUNE 24, 1873.)

This form of Ore Feeder is well adapted for its peculiar work.

Manufacturers of the Celebrated "Challenge" Ore Feeders for any character of ore; also "Stanford Improved" Ore Feeders and Tullock's Ore Feeders for dry ores.

DEWEY & CO.'S SCIENTIFIC PRESS PATENT AGENCY is the oldest established and most successful on the Pacific Coast. No. 252 Market St. Elevator 12 Front St., S. F.

BISHOP'S PATENT ELEVATOR,
FOR HANDLING BAGS OF GRAIN.

Address: 11 Stevenson Street, San Francisco.

With this elevator two men can elevate from 500 to 600 sacks of wheat in one hour from a warehouse floor to the top of the pile, 20 sacks high. It elevates every sack high enough to run them by a chute to any part of the pile, thus saving the labor of carrying. It saves the labor of four men to each pile. The elevator will raise sacks up to the tie beams of any warehouse, the machinery working under the beams. An ordinary laboring man will elevate 500 sacks per hour, and will do this labor with more ease than he could handle one end of each sack in the usual way. Two men will raise four sacks in the same time they raise one with the old style machine. This elevator is mounted on patent casters, making it perfectly portable over any warehouse floor, and can be secured at any place by a few turns of four spiral screws in the frame. It is always ready for use, without adjustment or change in any of its parts. All warehousemen who have seen this machine at work say it will save its cost in 30 days' use. It is well and strongly made, and with, with care, last from 15 to 20 years. It weighs about 400 pounds. These machines are guaranteed to do all claimed for them, if they are properly handled. On a single trip through Traver, Fresno, Merced, and Turlock, from one to three of these elevators were sold in every warehouse visited. In ordering machines, give light in feet and inches from the warehouse floor to the under side of the tie beams, and allow a few days' time for fitting up machines, which has to be done to suit orders.

IMPROVED FORM OF HYDRAULIC GIANTS.

The above cut illustrates the IMPROVED FORM OF HYDRAULIC GIANTS, which we manufacture. All similar styles are infringements upon this form, and a judgment stands of record to that effect, under the decision of Judge Sawyer of the U. S. Circuit Court in the matter of Hendy and Fisher vs. R. Hoskin et als.

Patents furnished upon application to

JOSHUA HENDY MACHINE WORKS,
39 to 51 Fremont St., San Francisco, Cal.

This cut represents our

IMPROVED
HYDRAULIC
MACHINE.

IT DIFFERS FROM THE OLD STYLE IN HAVING ONLY ONE JOINT instead of two. It is of greater capacity and more easily worked and kept in repair. The statement of Mr. Hendy that all styles are infringements on the machines made by him, he knows to be utterly false. All litigation has been in reference to old style two jointed machines, which are superseded by our new style one jointed. The decision of Judge Sawyer, referred to by him, is carried up on appeal to U. S. Supreme Court, with absolute certainty of a reversal in our favor. Send for Circulars and Price List.

HOOD'S FOUNDRY COKE.

Consumers are respectfully informed that owing to inferior brands of Coke having been sold in this and other countries under the name of "Patent Coke," the Glamorgan Coal Co. (Limited), Cardiff, in May, 1884, abandoned the title of "Patent Foundry Coke," substituting that of "Hood's Foundry Coke."

This Coke is exclusively used by the Selby Smelting and Lead Co., Union Iron Works, Professor Thomas Price, and other consumers here. Large quantities are regularly forwarded to Copper Smelters in Arizona and New Mexico, and also to consumers in Nevada and Salt Lake. The undersigned are the **SOLE IMPORTERS** of the above Coke, which is for sale in quantities to suit purchasers.

\$1,000 CHALLENGE!

**THE FRUE ORE CONCENTRATOR,
OR VANNING MACHINE.**

PRICE: FIVE HUNDRED AND SEVENTY-FIVE DOLLARS.
(\$575 00), F. O. B.

OVER 1,000 ARE NOW IN USE. Saves from 40 to 100 per cent more than any other Concentrator. Concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order and ready to make tests at the Fulton Iron Works, No. 220 Fremont Street, San Francisco.

As the result of a suit East against an End-Shake Machine (the Embrey), similar to the Triumph, the Frue Vanning Machine Company owns the Embrey patent, and can put in the market an End-Shake Machine of earlier patent that will do as good work as the Triumph, and superior in construction and durability. There will be no risk of suit for infringement.

The Frue Vanning Machine Company warn the public that they claim and will prove the Triumph machine to be an infringement on patents owned by them.

Protected by patents May 4, 1880, Dec. 22 1874, Sept. 2, 1879, April 27, 1880, March 22, 1881, Feb. 20, 1883, Sept. 18, 1883. Patents applied for.

N. B.—We are and have been ready at any time to make a competitive trial against the Triumph, or any other Concentrator for stakes of \$1,000.

ADAMS & CARTER, Agents Frue Vanning Machine Co.,

SAN FRANCISCO, CAL.

\$1,000 CHALLENGE ACCEPTED, PRICE, FIVE HUNDRED AND FIFTY DOLLARS (\$550.00).

**THE
"TRIUMPH" ORE CONCENTRATOR.**

The present improved form of the celebrated "TRIUMPH" Ore Concentrator possesses many advantages over any other style of Vanners, Vanning Machines, or Concentrators, yet introduced to the notice of mining men. These advantages consist in the superior features which enter into their construction, and facilitate their operation.

They are constructed in the best manner; their frames being of iron, insures their solidity, durability, and perfect steadiness of motion when operated. They are built as compactly as their requisite strength will permit, weigh less, require less freight space in boxes, by which their cost of transportation is reduced, and occupy less mill room when set up.

An important improvement has recently been introduced into their construction, which consists of a RIFFLE TABLE, placed in front of and which takes the discharge from the feed and amalgam bowl. The improvement is in the reciprocal motion which is imparted to this table by the longitudinal motion of the shaking frame to which the table is attached. We have at hand many testimonials, from well-known Superintendents of mines in different mining districts of the United States, bearing evidence of the efficiency and superiority of this form of Concentrator, and we shall be pleased to send Circulars covering such letters of testimony, and, as well, directions for setting up and operating these machines, and are ready to quote special prices for any considerable order.

The Baragwanath Steam-Jacket Feed-Water Heater and Purifier.

It is a generally conceded fact among engineers that an efficient feed-water heater is one of the most important factors in the economical production of steam, and yet, excepting in the larger plants, but little attention comparatively has been given to this subject, even on this coast where fuel is much more expensive than at the East.

The heater shown in the accompanying cut has many features of special merit and is one of the best that has been produced. Upward of 5000 of them, it is said, are in use in the Eastern States, and among the references given are many of the largest manufacturing establishments in the country.

The first desideratum in all appliances of this character is to raise the temperature of the water to the highest degree possible before putting it into the boiler. The second, to cleanse it of all impurities so as to avoid the deposit of sediment and the formation of scale.

The latter is by all means the most important consideration, as it is a well-known fact that there is little water, when subjected to proper tests, that does not show impurities to a very considerable degree, which, if carried into the boiler, are most troublesome and destructive. It is a fact, however, not so well known, that impurities held in suspension in the water are not precipitated until the temperature is raised above the boiling point.

Prof. Chandler, of Columbia College, one of the most noted chemists in the country, in a recent report to the New York Central Railroad Company as to the best means of purifying water for use in steam boilers, says: "Water, when boiled, expels the free carbonic acid and causes the separation of the carbonates of lime and magnesia, and if conducted at a high temperature and under considerable pressure, results in the almost complete precipitation of the sulphates of lime and other impurities."

Special stress, it will be observed, is laid upon the necessity of boiling the water under pressure before the impurities can be thrown off.

This is claimed to be what is accomplished in the Baragwanath heater, and is the only one that has demonstrated the possibility and practicability of so doing. This heater, then, has the advantage of imparting to the feed-water the highest degree of heat that is attainable by the use of exhaust steam, with no back pressure on the engine, giving in this way the greatest possible economy in the production of steam; as also that by boiling it under pressure all impurities, that are so destructive to the boiler, are eliminated.

This heater is warranted in every case to put the water into the boiler above 212°, and in the majority of cases at a temperature as high as 220°. This is made possible from the fact that there is no loss of heat by radiation, the water being confined in a close cylinder and surrounded by a steam jacket.

Another feature of special importance is that the steam does not come in contact with the water, thus preventing condensation and loss of heat. Also preventing the grease from the engine cylinder being carried into the boiler, producing foaming, a most troublesome and dangerous condition, as all engineers know.

Authentic testimony is brought from many sources to the effect that by their use boilers are kept clean and free from scale, and the

water being put into them at so high a temperature, a saving in fuel is effected of from 20 to 25 per cent.

For breweries, wineries, laundries, canneries, hotels and all other establishments where a large

MUTILATED SILVER COIN.—The mint, under instructions from the Secretary of the Treasury, receives mutilated and abraded coin by paying for it according to weight. The present price as regulated by circular is 96 cents an ounce.

THE BARAGWANATH JACKETED FEED-WATER HEATER AND PURIFIER.

amount of hot water is required, this heater would seem to be invaluable, from the fact that it delivers its water free from all impurities and with the greatest possible economy.

A. P. Brayton, Jr., 127 First street, has been appointed agent for the Pacific Coast.

THE Belmont (Nev.) *Courier* says: A revival in mining throughout Nye county is confidently expected. Mines that have long laid idle will soon be worked again for what is in them and not as a stock gamble.

Any person having had silver money can dispose of it at the mint for 96 cents an ounce. This is a good price considering the coin is nine-tenths fine. Bullion silver is bought by the mints at the price quoted by the London Exchange. Within the last few weeks there has been an unusually large amount of bad silver disposed of at the mint for the price mentioned. The money is packed in sacks and stored away. This is the only way in which mutilated coin can be got rid of by means of the Government.

Working Copperous Silver Ores.

Friedrich Ernst, of this city, has just patented through the MINING AND SCIENTIFIC PRESS Patent Agency a process for working silver ores containing copper for the purpose of extracting the silver therefrom. The ore is stamped or crushed in the presence of a hot aqueous solution of salt—such as sea-water heated—and the pulp is subsequently treated by amalgamation.

The copperous silver ore is placed in a battery with a quantity of hot salt water containing about three per cent of salt, such as common sea water. The hot salt water is used in the usual manner and instead of the fresh water commonly admitted to the battery. It may be prepared in any available way, though perhaps the least expensive would be to run the exhaust steam through a suitable condenser to heat the salt water, which should preferably reach the boiling point before being admitted to the battery. From the battery the pulp passes into the tanks to settle. It is then taken to the pans and amalgamated with quicksilver in the ordinary manner.

The essence of the process lies in the treatment of the ore with hot salt water, while still in the battery. The chemical action is as follows: The chlorine of the salt water forms, with a portion of the copper of the ore, chloride of copper, and with the silver it forms chloride of silver. The surplus copper acting on the chloride of silver precipitates the silver as native silver, and unites with the chlorine thus freed as chloride of copper. Thus the copper is entirely taken up by the chlorine, while the silver is left free. This is all done in the battery. Now, when the pulp treated reaches the amalgamating pans, the native silver, already separated, is easily amalgamated, and with little loss of quicksilver; while the copper which was in the ore, and which would also have been amalgamated and have produced a low-grade bullion, is prevented from amalgamating by its union with the chlorine. The result of this process is a bullion of 950 to 980 fine.

Of course Mr. Ernst is aware of the use of salt water in other metallurgical processes, and even in amalgamating pans; but his process is not to be confounded therewith, especially with the latter, for the presence of quicksilver in the pans essentially alters whatever reactions would be due to salt water alone; but by completing these reactions in the battery, and before the amalgamation, he frees the silver entirely, so that it may readily be taken up by the quicksilver.

He knows also that both hot and cold water have been introduced into the battery, and that carbonate of soda and some other reagents have been used, which effect a precipitation of the precious metals; but these have no application to this process, which is simply for the treatment of copperous silver ores by the introduction of hot salt water while the ore is being ground.

CAPTAIN C. F. DUTTON, of the United States Geological Survey, will spend about two months at Crater Lake, Oregon, this summer, making explorations. The general character of the country will be ascertained and the depth of the lake will be taken by soundings.

In the statistics of the production of lead in 1885 the amount is given at 130,667 tons, or about 9000 tons less than in 1884.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—EDS.

Montana Mines.

The Camp at Cooke City.

(From our Traveling Correspondent, R. G. Huston.)

Cooke City mines are located in Gallatin county, Montana, 60 miles northeast of Cinnabar, the terminus of the National Park Branch Railroad, and are on the head waters of Soda Butte creek, a tributary of the East Fork of the Yellowstone river. The altitude is about the same as the Hecla Consolidated, at Lion City, ranging from 9000 to 11,000 feet above the sea level.

The town at the present time contains a population of about 600, many of whom are millionaires in prospect, as is always the case in mining camps. The ore here nearly all carries a high percentage of lead; but the silver product is undoubtedly the main profit to be derived from this camp, and unless our congressional "dads" conclude to extend a helping hand and pass a resolution to permit the extension of the Park branch of the Northern Pacific to Cooke, so that the mines and smelters may receive the benefits aggregating from cheap transportation of coke and in bullion out, the immediate prosperity of the camp will be greatly retarded. The 60 miles wagon transportation comes very high, and during the winter season is stopped entirely, making it only a summer season camp. Consequently, it is only on a par with the old-time placers, so far as steady employment is concerned. There are a number of influential parties, who are using their best endeavors with the "powers that be" to get the bill for the extension of the road through, and if they succeed the product of the Cooke City smelter and mines will bring her before the public in a favorable light, beyond doubt.

The Great Republic

Is probably the best known and the most developed mine of any in the camp, and is located on Republic mountain, one mile south of Cooke. The ore of this mine carries a high percentage of lead and an average of 125 ounces of silver with a trace of gold; choice rock running as high as 400 and 500 ounces silver per ton.

This ledge is an immense ore body, being 20 feet wide at the surface, and has thus far been mostly worked by open cuts and at no place deeper than 200 feet.

The company have a 40-ton smelter on their property, which, at the present time, is shut down, owing to running short in their coke supply before the wagon road was open, and they are utilizing the time in making some necessary improvements in their plant, putting in roasters and a concentrator. The operations of this company are under the able superintendency of Mr. Richards, formerly of the Richmond, of Eureka, Nev., who brings to the Great Republic Company a wealth of experience gained in the Richmond Company operations, and will, no doubt, prove a valuable acquisition to the company in their future operations in and around Cooke City.

The Black Warrior

Is located four miles west of Cooke and is another of the immense properties in this district, carrying a width of nearly 20 feet and bearing silver carbonates and galena in abundance. It is owned by Harry Gassett and Messrs. Rading, Black and Randal. These parties are operating the old smelter and are now actively engaged in making all the preliminary arrangements for a full summer's work. Their ore carries a large percentage of lead and about 75 ounces of silver average to the ton, making it a very profitable property to work, with cheap transportation to and from material and product.

The Home Stake

Is a name synonymous of a rich find, and from appearances will be fully borne out in this instance. It is located on Henderson mountain, four miles northwest from Cooke, and is at an elevation of 11,000 feet above sea level. This property is owned by Mather Bros., the Bank of Livingston and Messrs. Smith and Huston. This is a very large contact vein, having one granite wall and one porphyry. This is still another immense body, and is a well-defined lead carrying a general average of 100 ounces of silver per ton. It is developed by a large open cut and two tunnels. It is at present under a bond of \$100,000 to some Eastern parties who are represented by Mr. Meader, formerly part owner and general manager of the Montana Copper Company, whose mine and works are located at Meaderville, some two miles east of Butte. The fact that this mine has attracted his attention is sufficient evidence of its value, if age and experience count for anything in expediting a mining property, and they are busy extending developments on the mine. There is little doubt that the bond will be taken up at this expiration.

The Shoo Fly

Is located on Miller mountain, two miles west of Cooke, and owned by Messrs. Miller, Moore & Pease. It is about 10 feet in width and carries about 50 ounces of silver and a very large

percentage of lead. This property was bonded by Messrs. Gassett & Co. for \$21,000, to expire October 1, 1886, and they have been energetically operating it, running two shifts of miners on it all winter. The general impression is that they will realize more than double the amount of the bond before it expires. This is certainly a good way to buy property, but such results are phenomenal and probably would not do to rely upon in all cases.

The Yate mine is near by and is owned by John Yate, Mather Bros. & Fuller, and is really a fine prospect, assaying pretty high, and it is being rapidly developed by a tunnel run to strike the lead at a depth of 200 feet. They are expecting to reach the lead with this tunnel by June 1st. If the outlook is as good at that depth as on top, the property will be one of the best in the camp, and the lucky owners will have their hands full for the time in getting a plant to work it.

The Young America

Is on Henderson mountain, four miles northwest from Cooke City. It is a silver-bearing lead, showing also a trace of gold and a percentage of copper and lead. It shows a fine body of ore on the surface, and is owned by Frank Essler and Judge Luce, of Bozeman, who are having a large amount of development work done, having a tunnel in nearly 400 feet. The average prospects on the surface are about 100 ounces of silver. If they find as good average assays at the depth at which they will strike it with their tunnel as on the surface, their future prospects will be assured. The amount of money these gentlemen are investing in this development work certainly makes them deserving of success. In running their tunnel they have crossed three small veins of black sulphurets, assaying as high as 200 ounces to the ton, but they are still pushing on for the main lead.

The Stillwater is situated in the mouth of Wolverine Pass, some five miles west of Cooke. It is owned by Messrs. Dewing, Bowen and Fleming, and is a four-foot vein of the richest ore discovered in the camp, carrying black sulphurets to the amount of from 200 ounces to 700 ounces to the ton. It is developed by a shaft 40 feet deep and levels run each way from it 50 feet. Their choicest ore is sacked and stored in the mine until such a time as they can get it out and ship it to the smelter.

The Roving Boy is on Miller mountain, one-half mile north of Cooke. It is owned by Dave Noble & Co., and is a contact vein, having lime and granite walls. It has about two feet of ore, assaying nearly 200 ounces per ton, and a trace of gold. The mine is developed by three shafts, none of which are over 50 feet in depth; but all have a fine showing of ore, making it a rather flattering prospect. There are a great many other locations here; but those noticed are the principal ones and the most developed.

The close proximity of these mines to the National Park should certainly bring them under the observation of many Eastern capitalists, and thus enable them to combine business and pleasure and invest their capital in Cooke City mines, when at the same time they visit the "Wonderland."

Experiments in Quartz Crushing.

EDITORS PRESS:—For some time I have been thinking that it would be well for one of these old gray-headed miners to take up the pen and give the younger ones some lessons founded on long experience. There is no truer saying than that history repeats itself—so do experiments in quartz. Now that a new generation of miners are around, some are beginning to find real things in ideas that were worked out 32 years ago and exploded. It is not my purpose to take up what I refer to above this time, but to comment on Mr. Louis Blanding's statement in the PRESS of May 29, 1886, wherein he gives "trial of quartz mills."

Blanding says 15 stamps do so much—one pulverizer does so much, and another pulverizer heats all. Now to an old gray-headed miner, who has got all his gray hairs from pounding quartz, or rather having quartz pound him, this is all hosh.

It's all hosh making tests without entering into every detail, to wit, labor required, power expended, size of ore received, size to which ore is reduced, if character of ore is same, and then wear and tear of iron. I am one who has been forced into the belief that nothing equals stamps, and it will take clean calculations as above to change this notion, and there are plenty more like me. So come down to business with your testing and let us old miners have something to surprise us.

Another item in the same issue, somewhat in the same direction, from the Sierra Tribune, I must comment on. It was headed "Quartz-Crushing Machines," and intended to give a hint to the University of California. It says: "Which crushing machine shall I buy? This question, every man who is about to erect quartz machinery, and wishes to do the best for himself or his company, is forced to ask himself. So far the answer is, nine times out of ten, in favor of stamps; but it does seem strange that in such a brilliant age as ours no improvement can be made on the primitive stamp.

"Now, we beg leave to ask our State University colon if it is not possible, amid all the experiments they are continually carrying on in

the interest of the honest Granger, they can do a little for the honest miner? We think it would be a grand idea for the School of Mines connected with the university to undertake to test the various machines now offered for the grinding of quartz, in order to furnish the miner with accurate information as to their value."

This is a brilliant idea for a mountain paper. How much of a test could the State University give all these machines? The place to test mining machinery is in the mountains, and not on one ton but 500 tons; if they heat stamps which have held good for 35 years in California, then amen.

The writer of that article does not know much about the "primitive stamp" or he would not write as he does. The "primitive stamp" of this State was a square piece of 6x6 oak or other hard wood, with a flat 2½ inches wide cut through for an uncouth-looking cam to play for lifting it. A square piece of iron for a shoe was at the bottom, which wore into all kinds of shapes, even like the sharp end of an egg. The mortar was low and cased in with wood and sheet iron. For sieves we used sheet iron, with holes punched by a punch or a pick. They were "sorry old stamp mills." Then we dare not run over 60 drops a minute. What have we now, and what are the improvements of this "brilliant age"? Splendid batteries; high motors; symmetrical cams; round stems; iron stems; revolving stems; gill tappits; steel shoes and dies, wearing true; 50 and 90 drops per minute, and narrow mortars. In fact there is nothing of the old California "primitive" mill left. We have all the time been on the march of progress. Every year has brought out some new features in stamp batteries, and so we are marching on.

Louis Blanding will "prick up his ears" at this, I suppose. He's good on testing ores, but he is up on testing machinery? At all events, we old-fisted miners are not to be caught with chaff. I don't want to be understood as opposed to any new machinery, but I do exact proper data in all this trial business.

THE OLD MAN OF THE MOUNTAINS.

Sonora, Tuolumne Co., Cal., June, 1886.

Montana Metals.

Superintendent Braden, of the United States Assay Office at St. Helena, Montana, has prepared a statement of the mineral product of Montana for the calendar year of 1885. He estimates the value of the various metals as follows:

Gold.....	\$3,400,400
Silver.....	9,171,984
Copper.....	9,000,000
Lead.....	2,000,000

Total.....\$23,581,384

Ten counties are credited with gold and silver. The largest product of gold was from Lewis and Clarke county—\$1,417,960—and the largest product of silver was \$5,335,504, from the Silver Bow county. The totals of gold and silver are apportioned among the respective counties as follows:

Beaverhead.....	\$1,000,190
Chateau.....	27,002
Deer Lodge.....	1,961,391
Gallatin.....	35,693
Jefferson.....	1,319,926
Lewis and Clarke.....	1,861,432
Madison.....	310,560
Miner.....	412,938
Missoula.....	39,746
Silver Bow.....	5,621,666

Total.....\$12,581,384

It is presumed that Mr. Braden's official position gives him good opportunities for getting at approximate results, and the above statement may therefore be relied upon. As to the copper and lead products, he is not so familiar with the facts, but believes the estimates sufficiently close for all practical purposes. The Anaconda, owned in this city, is the great copper mine of Montana. Most of the product is shipped direct to England.

THE DEEPEST MINING SHAFT.—The Combination shaft on the Comstock is now down to the 3200-foot level. The Combination is already the deepest vertical shaft on the continent of America, and there is but one other shaft in any part of the world that has attained a greater vertical depth. This deepest shaft in the world is the Adelbert shaft in the silver mines of Prizham, Bohemia, which at last accounts had reached the depth of 3280 feet. The attainment of that depth was the occasion of a three days' festival, and was still further honored by the striking off of commemorative silver medals of the value of a florin each. Twenty years ago very few mining shafts in the world had reached a vertical depth of 2000 feet. The very deepest at that time was in a metalliferous vein in Hanover, which had been carried down 2000 feet; but this was probably not a single perpendicular shaft. As for the deep shaft at Prizham, there is no record of the beginning of the work on the mine, though its written history goes back to 1527. When work on the Comstock shall have been carried on for 359 years, our shafts, at the present state of progress, will be knocking holes in the bottom of China.—*Don De Quille, in Salt Lake Tribune.*

WHEN it is believed a prospector has struck a bonanza every one extends a hand and invites him to take a drink; but when it is discovered that the bonanza was only an imaginary one, nobody notices him as he passes by.

Local Cable Railroad Notes.

The new Hayes-street Cable road, connecting with the Market street system, was opened for traffic this week. The road has been thoroughly tested, and, as soon as its new cars are ready, will be in perfect running order. The color of the cars and lights is green, and they will run through to the ferries. The company has erected a commodious engine and car house on the north side of Hayes street, between Masonic avenue and Lott street, and the finishing touches thereon will soon be made. A 300 horse power Corliss engine, capable of running 50 cars with 100 pounds of steam, has been placed therein and is furnishing the motive power.

The fact has been mentioned that the money has all been subscribed for the construction of the new cable railroad along Powell street, from Market street to the hay at North Beach. The contract for building the road has been let to Messrs. Wm. H. Martin and John Ballard, two well-known capitalists here, who have, within the past year, been heavy investors in city property. Messrs. Ballard and Martin, with three other men of means, own the whole franchise for the road on Powell street. Such a cross-town cable road has been needed for at least ten years. Real estate at North Beach has languished for want of it. A franchise for such a road on Powell street was given about five years ago, but the company was a paper one solely. The only work done was the laying of rails and the breaking of a portion of the sewer thereby, on Powell street, in front of Calvary church.

The published statement that the Sutter-street Railroad Company had forfeited its right to build a cable road on Ninth street, from Mission to Brannan, is denied by Secretary Stevens. He states that so far from the franchise being forfeited, nearly all of the preliminary arrangements for the construction of the extension on Ninth street have been completed, and as soon as it is decided whether the task shall be done by the company or contracted out, work will immediately be commenced thereon. The franchise does not expire until a year from next September, though the work would have been completed ere this but for the difficulty of obtaining from the Market-street company the privilege of using the concrete method of constructing the road-bed and cable tube. This privilege, with others almost equally desirable, has now been obtained.

Upon the completion of the Ninth-street extension the work will be commenced of extending the cable road on Polk street through to Union street, and thence to the beach as soon as the blocks north of Union are graded.

It is the intention of the company to use steel rails exclusively hereafter. The rails on Sutter street, between the ferry and Polk street, are now of that metal, and the work of replacing with steel the iron rails east of Polk will be commenced within a couple of days, the new rails having been already distributed along the line.

In last week's PRESS we published the articles of incorporation of the Pacific Cable Railway Co., in which the directors are Leland Stanford, A. S. Hallidie, Charles F. Crocker, F. F. Low, James Moffitt and J. L. Wilcutt. The capital stock is \$2,000,000. Mr. Hallidie, one of the directors, states that the object of the incorporation is to amalgamate all the patent rights of the different cable companies of San Francisco, and thus terminate the endless legal strife at present arising out of the infringements of patents. The first cable railway constructed was that on Clay street. In 1875, owing to several improvements in Mr. Hallidie's patents having taken place, a corporation was organized to purchase and protect them. It was called the Traction Railway Company, and in it Mr. Hallidie held a considerable interest. In 1877, owing to still further encroachments on the rights of the patent-holders, suits were instituted and judgments obtained against the Geary-street and Sutter-street Cable companies. Then another corporation was formed, which succeeded to all the rights of the Traction Railway Company and was incorporated under the title of the Cable Railway Company. In 1883 the Market-street Cable Company was organized and became the possessor of various independent patents, including that of Henry Root. This was the last company formed with patent rights, and owing to the number of patents existing, and their great similarity to each other, numerous expensive lawsuits were instituted. This, of course, seriously hampered the construction of new cable roads, as corporations about to build were slow to purchase the patent rights from either company, fearing to become involved in a costly legal suit with the one whose patent they had not bought. To end all this is the object of the new incorporation. It is expected that the formation of the new company will give a great impetus to the construction of cable roads throughout the country.

FALLING BODIES.—As illustrating the force of a small object falling from a distance, it is said that a shot dropped from the dome of the State Capitol at Des Moines made a clean, neat hole through the inch-glass floor in the rotunda. The Blade says that last winter a lady accidentally dropped a heavy muff from the same distance, and when it struck the floor below the noise was heard all over the building and some supposed a gun had been fired off.

Alaska Mining Notes.

The mill at Douglas island is running at its full capacity day and night and ships \$83,000 in gold bars for the last month's work. It will do better in future, as some very rich rock has been struck on the line between this property and the Bear's Nest mine.

This placer excitement in Sitka grew out of the discovery of good gold indications in the gravel in a gulch not far from the beach at Jamestown bay, by Messrs. W. J. Prout and A. A. Starwalt. These gentlemen have gone down 16 feet and struck a stream of water which temporarily stopped their work. But they are providing force pumps and will prosecute the work to a full test. The indications continue good, and they say they will find the bed-rock in spite of the water or "bast."

The *World's* Washington special says: The Secretary of the Interior has received through the acting Secretary of Alaska, and indorsed by him, a petition from the miners and prospectors of Harris' mining district, which represents that large numbers of miners and prospectors have left and many others are preparing to leave that section for the recently discovered Yukon river gold diggings; that in order to reach their destination they must pass through a section of country inhabited by the rich and powerful Chilcat and Chilcoat tribes of Indians; that these Indians arrogantly demand exorbitant sums for their services in packing supplies across the Chilcat portage and threaten to prevent by force any other Indians from engaging in this service. The petitioners ask for relief. Trouble is feared, and at the request of the acting Governor of Alaska the United States steamer *Pinta*, under Lieutenant-Commander Nichols, has gone to Chilcat inlet to preserve the peace.

A correspondent of the *Chronicle* furnishes the following about the mining affairs of this Territory: Arriving at Sitka on the 13th ult., I found the capital city far more quiet than I had ever seen it before. Its inhabitants, however, were jubilant over arrangements being made for the opening of quartz mines at the head of Silver Bay district, distant 13 miles east. These mining locations are likely to demand the expenditures of some capital, but if I understand the ground they will never pay a dividend. Beyond this possible chance for a mining boom, Sitka has nothing to build upon. There may be a few garden patches through the town, but there is no agricultural range to back it up, notwithstanding recent published statements to the contrary. Being a port of entry, and at present the seat of our Territorial Government, many have been misled as to its commercial importance, but with this foregoing facts its future may be easily rated.

Owing to the stampede of miners to the new diggings of the interior, this town is every day like Sunday. About 110 men have already left here in search of the golden phantom. For several years different parties have been finding a little fine gold on the bars along the tributary streams of the Yukon river, but no gravel diggings have yet been discovered. I am in possession of all the facts connected with the asserted discovery of last season, which resolve themselves simply into an effort to attract travel hither. It would therefore be well for mining men to wait the result of those already off on this stampede before arranging for a trip to Stewart river. The expense, route and many obstacles to be encountered should be carefully considered.

The route from here is by boat or canoe up Lynn canal to the Chilkoot mission, distant 90 miles; thence, with Chilkat Indians as packers, up and over the Chilkoot pass to the head of the first lake, distant 35 miles, and thence by small boats down the lakes and river to Stewart river, distant 450 miles. Total distance about 575 miles. These Indians are charging 12 cents per pound for packing from the mission to the lake, and as they do not allow any one else to pack over this trail they have an ironclad monopoly of the business—in fact, the miners are not even permitted to pack their own blankets. At the lake, lumber must be whipsawed for boats, after which they are built. Necessarily each party is obliged to take in saws, axes and nails. The cost of supplies for the season and packing over the Chilkoot pass may be rated at \$2.50 per man from here; therefore this stampede has already cost the participants about \$27,500, the majority of whom will ever regret their trip to the interior.

The placer mine owners of Silver Bow basin will not be able to resume operations before June, owing to the lateness of the season. There will not be more than eight mines in operation, one-half of which will be worked out before the end of October next. The entire output from the basin this season will not go beyond \$40,000. As there are no quartz mines in the basin, though there are many locations, none of which will ever develop into the condition of paying properties, the outlook for this camp is not very expensive.

The mine and milling operation on Douglas island, locally known as the Treadwell mine, is continuing its regular monthly dividend of 25 cents per share. It is beyond doubt an immense surface body of low-grade ore. Doubtless the extensions will prove equally as valuable. The operations of this company have been and will continue to grow more conservative. There are about 75 Chinese employed about the mine, at the rate of \$1.50 per day each. Necessarily there are but few white men

in the company's employ, outside of the logging camp. A large building has just been completed for the company's merchandising establishment, which, when in operation, will draw the entire Indian trade from Juneau. Therefore the merchants here would like to get away, but can't leave owing to many circumstances peculiar to their method of doing business.

Notwithstanding the recent statements made about the great agricultural and pastoral possibilities of Alaska, especially the southeastern portion of this Territory, there is not, cannot, and therefore will never be the one or other. From present indications, the industries of the Territory will continue for the next 25 years as they are now. Fur, fish and mining, and, if I mistake not, the quartz-mining operations of the interior, will yet astonish even the bonanza operators of the Comstock lode.

Under existing circumstances, while there are even now opportunities for the investment of capital, Alaska is no place for poor men; in fact, there are far too many here already, many of whom would gladly leave the Territory if they were furnished with the necessary means. For summer tourists the inland or island passages to Sitka and return will ever seem a wonderland. These magnificently grand panoramic scenes of nature should be seen by all who can afford a summer tour.

Bullion Product of Colorado.

The Superintendent of the United States Assay Office, at Denver, has been making some figures as to the bullion yield of Colorado for the calendar year of 1885. These totals are made up from returns of the smelters, ores shipped from the State, purchases at the Assay Office and sales to manufacturers. The gold and silver product is given as follows:

Gold.....	\$ 4,000,800
Silver.....	15,427,973
Total.....	\$20,097,372

The silver mines of Colorado, especially those of Leadville, carry considerable lead. The product of lead for 1885 is stated at 51,550 tons, valued at \$4,124,000. Colorado has not done much in the copper line, yet we notice a value of \$256,936 for that product in that State last year. This swells the total value of the bullion yield of Colorado for 1885 to \$24,432,008, and places the State a little ahead of Montana. The *Mining Record* regards the figures for gold and silver in Colorado about \$2,000,000 too much, the excess being nearly evenly divided between the two metals. It is evident that Colorado and Montana are at present the leading bullion producers of the country. California still holds its position as the leading gold State, but Colorado is the leading silver State, and Montana leads all other Pacific States and Territories in copper. Nevada has fallen behind as a metal State in the last few years, yet the product of the Nevada mines is no small item in the grand total. It is to be hoped that better days are in store for the Nevada miners.

THE CUT IN COPPER.—The Butte (M. T.) *Inter-Mountain* says: Information was received by telegraph Monday evening to the effect that a cut has been inaugurated in the price of copper by the Lake companies, with the Calumet & Hecla in the lead, and the copper of that region was quoted in New York Monday at 10 cents, a drop of nearly 1½ cents. The object of this break is to try to close down all other copper mines in the country, and especially is the move aimed at Butte. While it may result in shutting down some of the mines in Arizona and other sections, the only effect it will have upon Butte will be to cause a large increase in the output. The Butte companies will of course have their profits on their present output considerably decreased, but it will meet the bluff by largely increasing its output so that the average monthly profit will be at least equal to what it was before. By increasing their output there will also be a small proportionate saving in the cost of production, and all of these things together will enable them to meet the play of the Lake companies in a manner that will make the Calumet & Hecla and other companies of that section sorry. The president of the Calumet & Hecla has gone so far as to advise Vice-President Oakes, of the Northern Pacific, not to extend that road to this city, because Butte will be hurt up in business in a very short time. It is understood, however, that Oakes gave him such an answer as will convince him that he knows less about railroad matters than he even does about hearing the copper market.

MINING IN THE NEW RIVER COUNTRY.—The present available grinding capacity of the district consists of eight arrastras and one five-stamp mill, all of which are running on rock that will pay from \$20 to \$185 per ton within two weeks, and with the increased facilities now in view the bullion production of the camp will be quite an item by fall. Unlike many mining camps, where the prospector and discoverers of the ledges are seldom able to reap the benefits of their labors on account of the hardness of this rock or difficulty in working the ore, the surface of the ledges here is soft, the gold is free and can be easily saved in the "poor man's mill"—the arrastra. Thus the chances to "freeze out" the discoverer in this camp, as is generally the result of many cases in older and perhaps richer

districts, will stand a very poor show here. The feeling among those who are interested in this particular camp is one of complete satisfaction with the prospects.—*Corr. Trinity Journal.*

About Ore Concentration.

The following extracts from a letter received by the *Virginia Enterprise*, from a gentleman of extensive milling and mining experience in Colorado, as well as on the Pacific Coast, contains well-considered and useful practical suggestions which will be read with interest. What he says about roasting rich bonanza ore from the Comstock is well worthy of consideration. It being a private letter, not intended for publication, we are not authorized to give the gentleman's name. He writes from a mining county in California, where he is operating at present: "I agree with the *Virginia Enterprise* entirely in its remarks relative to the impossibility of concentrating the chlorides of the Comstock by means of the patent machines now being introduced. They may succeed in concentrating the sulphurates, gold and similar metallic combinations to a certain extent, but the chloride ores forming the great majority of the Comstock they necessarily have to totally fail in concentrating.

"There are certain minerals, combinations of metals and minerals, and conditions of metals, which so alter their specific gravities that they will float or remain suspended in water. To attempt to concentrate such material in water is a manifest absurdity, and yet all inventors of concentrating machinery attempt to do this thing, apparently on the principle that gold or silver in any condition, because it is valuable, must necessarily be heavy. Tellurium, in combination with gold and silver, breaks up in crushing into the finest powder and floats off, and no form of wet concentration has yet saved it. The telluride ores of Boulder county, Colorado, illustrate this fact.

"Certain combinations of selenium and gold and tellurium and gold in California do the same, and chlorides of silver are in the same category. Metallic gold may be so fine as to escape both amalgamation and concentration, and can be saved only by chlorination, solution and precipitation, as is the case with certain of our own ores at this place.

"In the year 1876 I had some of the bonanza ore from the Consolidated Virginia or California mine sent me to my mill in Colorado. Its composition was free gold, gold combined with sulphuretted iron and chlorides and sulphuretted silver. Its value was \$135 per ton, and in milling, according to the report of the mine for that year, if my memory serves me right, not over 60 per cent was saved. I roasted it in my furnace, and found that chloride and sulphuretted combinations were broken up, and metallic gold and silver were formed. I had and have no doubt that in this way of treating the ore, followed by concentration, very nearly all the precious metals might have been saved at a quite reasonable cost. I doubt, however, if the very low-grade ores of the Comstock could be treated profitably in that way. It is too late to talk about saving values in bonanza ores when there are none, and not less absurd to go fishing for those lost values in the Carson river. I know something about that extensive dredging scheme and its projectors, and you can chalk it down for a predestined, unqualified failure."

KEEPING WATER OUT OF A SHAFT.—Another important mining scheme has just been begun here at Oroville. The idea is to sink a shaft and from this drive down a tube so as to work certain ground that has hitherto never been worked on account of the water. This is the same process that has been successfully used in sinking for foundations for bridges in certain localities. On top of the ground is a mighty air compressor, and from this pipe will lead to the working shaft. There are several sections of large tubes that look, to the uninitiated, like large engine boilers with the ends knocked out. The air pipe will run through these in such a manner that any degree of air pressure can be obtained that is desired. The pipe will have an apparatus similar to the faucet on a water pipe, so that the amount of air can be regulated by the workmen in charge. The men will be admitted to the first section and the valve closed behind them, and then an increased amount of air will be forced into this section. When the men have been accustomed to this for a short time, they will be admitted to the second section and then to the third, till they become able to stand a pressure of air so strong that it will keep back the water. Of course it will take rich ground to make a mine pay worked under the disadvantages of this plan, but there is a large amount of very rich mining ground that has never been touched on account of the trouble with water. The new works will be placed near Montgomery street, and the tunnel will be run under the hill back of Mrs. McCallan's residence. Work has just begun, and all the machinery has not arrived, but enough is here to show what the plan of working will be. This style of mining can do no damage, and will give employment to a large number of men, so that we hope to see it prove a grand success.—*Oroville Register.*

THE ARGUS MINING COMPANY, of Taylor, White Pine county, Nevada, shipped lately through Wells, Fargo & Co. ten bars of bullion valued at \$21,247.60.

Forestry Congress Meeting in Denver.

The next meeting of the American Forestry Congress will be held in September in Denver, Colorado. The next move ought to bring this Congress to California.

We have just received from Secretary B. E. Fernow a preliminary circular announcing the Denver meeting and calling upon all interested in Forestry to prepare papers for the meeting and to announce their intention to attend. The exact date of the meeting will be stated hereafter. Meeting in an arid State like Colorado, there will naturally be much brought forward which will be of practical interest in California. The questions, whether and how far the influence of forest cover on water supply can be established; whether and how far forest growing will change agricultural conditions in the arid region; whether and how far forest culture is there possible, and what the proper means of the reforestation of these wastes may be—these are questions of the greatest moment.

The secretary announces that the program will be so arranged, therefore, as to give ample opportunity for the presentation of actual experience and a discussion thereon; and the number of topics for papers of a speculative character will be limited to the following: 1. Relation of forests to water supply. 2. Methods of management for a natural renewal of Rocky mountain forests. 3. Methods of tree-planting in arid regions and the plains. 4. Profits of forest culture. 5. Possibilities and aims of forest experiment stations. 6. State and national forest legislation.

Upon another page of this issue will be found an essay by Mr. Fernow, which gives very important data concerning the value of forest conservation and extension in a country, depending upon irrigation for its agricultural development.

The economy of crude oil as a fuel is daily demonstrated at the Capital flouring-mills, Los Angeles, with its capacity for turning out 250 barrels of flour every 24 hours. A box-car, containing two tanks of the oil as it comes from the earth at Newhall, is run up on the track to the engine-room, where a pipe is attached which carries the dark substance direct to the injectors at the furnace doors, where it is blown in by jets of steam, creating an intense heat which develops steam to run the 200 horse power engine at a speed of 75 revolutions per minute. The *Los Angeles Herald* states that the amount of oil required is eight-tenths of a quart per hour per horsepower, or 40 gallons per hour when the full power of the engine is developed. Eight-tenths of a quart of oil is equivalent to 2½ pounds of Australian coal, which costs \$16 per ton in Los Angeles. In addition to the greater cleanliness, the services of a fireman are dispensed with at the mill. It would seem that other manufacturing establishments might adopt this fuel to advantage.

FURNACE.—The Belmont *Courier* says: The furnace lately purchased by the Giant Mining Company, at Park Canyon, of the Citizens' Mill Company, of Austin, is now in place in the mill of the former company. The roasting of its ore is now conducted with a double furnace under the T. J. Ball and A. Griffith patent. The company has demonstrated the fact that by the method of roasting used by it under this patent it can work its most refractory ore to about 92 per cent of its assay value. This is a splendid showing and result on this ore, which is considered one of the "hardest nuts in the country" to crack. The mine is showing a large and extensive ledge of ore which the Giant Company is now mining with a full force of men. The ore is of good grade and almost inexhaustible in quantity. This property, as well as its neighbor in Ophir, bids fair to make Nye county lively during the present year and add greatly to our bullion product.

ASSAYING A DOG.—John O'Neill is always a very quiet man about stocks, and if John hasn't got a pointer on Mono now, no one has. Everybody in this camp knows Towser, the Mono mine Towser. This dog Towser rides up and down on the cages, through drifts and crosscuts, and goes all over and through the mine perhaps oftener than any miner of them all. Yesterday a brilliant idea struck John and some others, and they spirited Towser into a hack yard. They washed his hair as clean to the skin as it possibly could be washed, and then carefully panned the muddy water to the very highest percentage, and the entire dog absolutely assayed in fine gold \$23.17, as weighed on Soderling's scales. When Mono assays \$23.17 to the dog, she is certainly starting out on a boom, and we defy any mining camp on the Pacific Coast to beat it.—*Bodie Miner.*

FRESNO MINING DISTRICT.—From Mr. G. W. Fuller, of the Rocky Bar mine, we learn that mining matters are active in that locality. The mountains are full of prospectors, new lot-cations are being made every day, and all that are being developed so far show satisfactory evidence of richness. A five-stamp quartz mill has just been put up at the Rocky Bar, and commenced work with over 70 tons of rock on the dump. Twelve men are now employed at this mine, and the deeper down the lead is followed the broader the vein becomes, and the rock also becomes richer. Rev. Mr. Meserve, of this city, is interested with Mr. Fuller in this fine mining property.—*Fresno Republican.*

Passing Events.

Although the Comstock mines are not paying dividends a good deal of money is being taken out there. The payrolls last month amounted to \$218,538—a large sum to be paid out in one camp for hands in mines and mills.

The Attorney-General has rendered an opinion in regard to the authority of the War Department to take action against hydraulic miners who cause the debris of their work to flow into navigable streams that are being improved by the Federal Government. The Attorney-General holds that there is nothing in the present law that warrants such action on the part of the Secretary of War. The River and Harbor Bill anticipated this decision and contains a provision which instructs the Secretary to institute proceedings against such offenders.

The disturbed condition of affairs in India keep the silver market in a state of fluctuation. The first decline in silver for weeks was occasioned by the Indian Council getting \$100,000 silver below their limited price, and the decline last week was, no doubt, a repetition of the Indian Council's tactics.

The Fire Patrol Salvage Pump.

A new and very powerful salvage steam pump has been recently completed by the Dow Steam Pump Works of this city for the Underwriters' Fire Patrol. The purpose of the pump is to free flooded basements or cellars of buildings of water, which may have accumulated there from fire engines, where no outlet has been provided to carry the same off into the sewers by suitable pipes. Some of the more recently constructed buildings in this city have been provided with these outlet pipes, which are a safeguard against flooding from rains or bursting pipes, and in case of water from fire engines. These outlets are, however, liable to derangement and to choke up.

In the case of the Crocker fire on Bush street, the basements of the whole block were more or less flooded for several feet in depth by the immense quantity of water poured into the burning building and no adequate means of at once freeing the accumulation of water. The consequence was that something like \$75,000 of damage by water to the goods in these basements was done in a few houses, and the insurance companies were compelled to pay the damage, as it was caused secondarily by the fire in the adjoining building.

To obviate the recurrence of this disaster, Mr. Wm. McDonald, agent of the Connecticut Fire Insurance Co., suggested to the Directors of the Underwriters' Fire Patrol, of which he is a member, to have constructed a powerful low lift steam pump, mounted on wheels, which could be available in a similar emergency. The subject was taken into consideration, and a contract made with the Dow Steam Pump Works for the construction of the pump.

A brief description of the pump is as follows: The boiler is an upright tubular, 30 inches diameter and seven feet high, and contains 1½-inch tubes—in a submerged tube head—and has 175 feet of heating surface. The pump is a vertical plunger, 16 inches in diameter and 18 inches stroke, working in an annular ring, in an interior case. This interior case carries the valves, 32 inlet and 32 outlet; a vertical diaphragm partition dividing the inlet and outlet sections. An exterior case makes, with the interior case, an annular space of about four inches into which the water flows from the suction pipes and thus furnishes water to the suction valves arranged around the half circle of the suction side. The area of these inlet valves is about 25 per cent in excess of the area of the plunger, so there is a minimum amount of friction in the water passages, and the valve seat easily and freely. The outlet is arranged in the same way.

The pump is made in halves, horizontally, and bolted together by a flange connection. The bottom is also similarly arranged, so as to get at the pump interior. Hand-holes are also made to get at the valves. The whole pump is made of the best gun metal (copper and tin). The steam cylinder is 10 inches diameter and 18 inches stroke, and arranged with Dow's patent valve motion, and will make 128 strokes per minute, drafting water from 25 feet and discharging 2000 gallons per minute at the pump level—as much as three or four Amoskeag fire engines can pump in the same time through 1½-inch nozzles. The power of the salvage pump being for lifting a large quantity of water from a depth of, say 20 to 25 feet, and the fire engine to force a smaller quantity to a distance or height.

The whole machine is mounted on wheels similar to a fire engine, but it is so arranged that when at work the weight rests directly on the ground, avoiding the jar that would otherwise occur did it remain with the weight on the wheels.

The weight of the pump complete is about 9000 pounds, and is handsomely finished with lagging and Russia sheet iron casing and brass hands, and brass dome on the boiler.

The whole machine has a light and graceful look, although so powerful and strong. The suction can be taken from two or one seven-inch flexible suction hose as required—and a draft from two adjoining basements if necessary.

A pump similarly arranged and constructed by the same builders is in use as a circulating pump in the United States steamer *Rush*, and gives great satisfaction.

THE Grand Prize at Tuscarora has shut down.

Working Gold-Bearing Sulphurets.

Concentration and Chlorination in Nevada County, Cal.—No. 5.

(Written for the PRESS by C. A. SCURNEK.)

Leaching the Ore.

In some camps it has been the experience that if rich auriferous silver ores, in which the percentage of gold is high, almost equal to that of silver, are subjected to a chloridizing roasting, then impregnated with chlorine gas, leached with water for the purpose of extracting the gold, and finally leached with hyposulphite of lime for the purpose of extracting the silver, the yield in gold hardly amounts to much more than about 50 per cent, more or less, although a high percentage of silver is extracted. This is not in accordance with the experience of the metallurgical works in this district, where the roasted ore is first impregnated with chlorine, then leached with cold water for its tenor of gold and then leached with hyposulphite of lime for the silver. The roasted ore after cooling is passed through a coarse sieve, eight holes to the running inch, for the purpose of separating the lumps which have been formed during the roasting, and also for separating impurities, such as nails, pieces of iron which might have been accidentally mixed with the ore. The sifting is not done into the vat, which is the rule in other districts, but on the brick floor, the sieve standing on the latter in an inclined position. The separated lumps are recrushed and added to a new charge in the furnace for the purpose of being roasted over. The ore of which these lumps consist is only imperfectly roasted, so that the gold which they contain would be in a state not to be acted upon by chlorine, even if recrushed, if they were charged into the vat without re-roasting. They would, moreover, cause a still more serious loss from the ferrous sulphate of iron resulting from the imperfect roasting of lumps. In the gold-leaching vat this sulphate of iron would be dissolved in introducing the water and precipitate some of the gold in the vat, which would be almost entirely lost, as little of it is redissolved in the subsequent leaching with hyposulphite of lime.

The roasted and sifted ore is now spread out in a layer on the brick floor and

Moistened With Water by Spraying

It over the surface to such a degree that the ore does not dust any more after working the water by means of a hoe well into the whole mass. This is done for two reasons: first, the chlorine does not act as vigorously on dry ore as it does on moist; and, second, dry ore would pack more in the vat than ore which is just moist enough, so that it doesn't dust; the former offering consequently more resistance to the ascending gas, and unnecessarily increasing thereby the time of working a charge in the vat.

It has already been stated that the roasted ore is not sifted into the vat at the Providence and other chlorination works around Nevada City; it is charged into it by means of a square wooden box, holding about 50 pounds of ore. After filling the box from the prepared ore lying on the brick floor, the workman transfers the charge into the vat, where he dumps it on the prepared filter. Charging the vat in this careful way makes it sure that the mass of ore is in as light and porous condition as can be.

The Filter on the False Bottom

Is prepared with old gunny sacks. In a damp condition they are spread out on the floor, so that the latter is covered with one, or better, two thicknesses of them. At the sides the cloth is drawn up from two or three inches, forming a ring which is held in place by the wood on one side and on the other by a ring of ore, which is slightly pressed by hand to the cloth. By this means the gas is prevented from ascending quicker on the sides than toward the center, and also that the leaching water works through here faster than at other places, disturbing perhaps the filter and carrying with it more or less of the ore, which would run with the filtrate into the precipitation tank. No gravel bottom is used in preparing the filter.

All the Tubs

Are painted inside and out with three coats of liquid asphaltum varnish—the false bottom also—which should be renewed every year. The tubs are charged with 2½ to 3 tons of ore, which fills them to within three inches of the cover,

which is now put on by the aid of a tackle, which hangs from a small truck, traveling on a suspended track over the whole line of tubs. When the cover is set into its place, the circular groove left around its edge is calked with rags, and the joints are wetted and luted with plenty of tough dough, which is kept moist by a covering of wet cloth.

The gold chlorination tubs have the following dimensions: Diameter at top, 5 feet 9 inches; diameter at bottom, 6 feet 3 inches; depth to the false bottom, 3 feet. The bottoms are made of three-inch planks tongued together; the staves are of two-inch stuff with plain joints; a hatten three-quarters by two and one-half inches is laid over each joint; four iron hoops are driven hard around all. The false bottom, one inch above the true, is made of one-inch boards, perforated with one inch holes. By means of a short piece of lead pipe, a so-called lead nipple and a one-half-inch rubber hose, the gas is led from the generator into the tub below the false bottom. From a wooden faucet, which enters also below the false bottom, the gold solution is conducted by means of a rubber hose to the precipitation vats. The chlorination vat is slightly inclined toward the discharge side to insure complete training. The false bottom rests on strips of wood, which are made thicker at one end than at the other, so that it is horizontal.

Foundry Notes.

Business at the foundries continues rather dull. A few months since there was a little "spurt" of work, and it was hoped the long-looked-for advance in business had come, but it has dropped back into the old groove again. There is more or less work going on, of course, at all the foundries, but there are few large jobs in progress.

The steel armor plate made recently in this city and sent to Washington for exhibition, to show that armor plating can be made in this country, is attracting considerable attention. It is eight feet six inches long, two feet six inches wide and ten inches thick. It is of hammered steel, end was cast at the Pacific Rolling Mills, the planing, trimming and finishing being done at the Union Iron Works. It shows that the Union Iron Works can get all necessary material here for building armored vessels in California.

The contract for the great steel dome of the Lick Observatory on Mount Hamilton has been awarded to the Union Iron Works of this city for \$58,850. The dome will be 76 feet in diameter. The iron plate on top of the brick will weigh 37 tons. The moving part of the dome will weigh about 90 tons with wall plate, 127 tons in all. The bid of the Union Iron Works was \$56,850 to construct end set up the dome complete. The Eastern bid for this was for the work to be delivered in the maker's workshop, and after figuring the cost of transportation and erection on Mount Hamilton, the California firm not only submitted by far the best design, but was the lowest bidder, and the sequel shows that California is in the front rank of progress. It is the hope of the trustees that in one year from next August the Lick Observatory will be turned over and become one of the great institutions of this State, with a surplus from the endowment fund of \$200,000.

The Pacific Rolling Mill Company, of San Francisco, has entered suit at San Jose against the Saratoga & Alameda Railroad Company for recovery of amount due for supplies furnished.

RESIDENTS of Virginia City are alarmed at the settling of buildings owing to the caving of underground drifts and the giving way of timbers. Dr. A. M. Cole recently had to remove the plate glass from his show windows to keep them from falling out. On examination there was found to be a space of two inches between the top of the plate glass and the window frame.

THE Virginia City, Nevada, papers say that the new find at the foot of Six-mile canyon, known as Pfeifer's ledge, is barren of metal as far as prospected. The ledge is a blind one, and locations have been made toward every point of the compass.

At the United States Assay Office at Helena, M. T., recently, 1823 ounces of gold were received in two days—the largest amount for the time known in the history of the office.

Price's Bullion Rooms and Ore Floors.

Professor Thomas Price is well known all over this coast from his long connection with the mining interests, both as an examiner of properties and as an assayer and analyst. He has been in the business in this city since 1862, and in his present quarters, No. 524 Sacramento street, since 1875. No establishment of the kind in San Francisco is better known, or has better facilities. The building is a large one, and is entirely devoted to Professor Price's business, being so arranged that the various departments on the two floors are properly separated, while at the same time the professor can exercise a proper supervision over all. The numerous employees are all skilled in their several branches, and most of them have been with him many years. Many persons in the mining regions have had business and correspondence with this establishment without being able to visit it, and to them a brief description will be of interest. The business naturally divides itself into three departments: the bullion, the metallurgical and the chemical.

The Bullion Department.

The department includes the receiving of bullion, melting, assaying and refining. The bullion is received in all shapes, crude and otherwise. The base metals are separated and it is put in such a condition that its value can be determined, in order to realize the highest possible price. Professor Price does not buy bullion, but prepares and offers it for sale, so that the highest bidder each day can procure it. In this way the bullion owner gets the benefit of the highest ruling price of the market. Both gold and silver fluctuate in value more or less on account of the demand for exchange, and there is more or less speculation in silver on account of the fluctuation. For the refining of gold they have lately added to the establishment the well known Miller process, which is that used now in all the Australian mints, all the gold in that country being refined by that method. Having lately secured the patents for certain methods for refining by the sulphuric acid process, a complete department in that direction will soon be added. Attached to the bullion department is a complete and separate assay office for conducting that work by itself, without coming in contact with the ore assaying establishment. Now that the U. S. mint is closed for its annual settlement, the bullion department is kept busy. Miners will be enabled to get returns from Professor Price more promptly than from the mint, and bullion may be deposited in the same manner.

Metallurgical.

The metallurgical department is fitted with an extensive ore floor, with ore crushers and pulverizers, for the crushing and sampling of ores, amalgamating pans for working tests, and facilities for testing any process for the extraction of gold and silver. There are special furnaces for smelting rich ore and other products, such as sulphides of silver produced from leaching process works, etc. Arrangements are made also for handling jewelers' sweeps, photographic liquids and paper, etc., by special methods, by which it is possible to realize the maximum values for these and similar products. Particular attention is paid to the concentration of ore with a view to ascertaining the best form of concentrator according to the nature and character of different ores. Assaying in all its branches and analysis of ores are conducted in this department.

The key to the proper treatment of all ores is a full knowledge of their composition. The analysis should be the very foundation of any plan of treatment, since to work the ore properly its exact character should be known with all its constituent parts. This fact is better realized now than it has been and more ore analyses are being made in consequence. The facilities for this work are very complete.

In this connection it may be stated that now this and other cities are putting more stone into buildings, the character and permanency of the building stone should be thoroughly examined. Its power to resist the action of the weather and of fire should be tested, and for these points much depends on the character of the component parts. New cities should reap the benefit of the experience of others, and the properties of our peculiar building stones should be tested.

The Chemical Department.

This consists of the chemical laboratory with

all the appliances and apparatus for all kinds of analytical work. A particular specialty is made of analysis of food, drink and poisons and all industrial products. The laboratory is very completely fitted up with the apparatus necessary for performing both organic and inorganic analyses of everything that presents itself. Investigations will be undertaken of chemical processes of any kind. Prof. Price will make estimates and prepare plans for the construction of works and factories for the manufacture of chemical products of all kinds, and examine into the character and nature of all by-products and their utilization. Analyses are also made of mineral and domestic waters, etc.

All these departments are personally supervised and conducted by Professor Price, and numerous skilled assistants, chief of which is his son, Arthur Price, who has studied his profession in the leading chemical schools of England and Germany. The appliances and apparatus are all of the best in each department, and the whole establishment is conducted on a scale commensurate with its importance. While a large portion of the work is that connected with the assaying, refining, sampling, testing, etc., of ores and bullion, as may be seen, all matters relating to sanitary and industrial chemistry are carefully attended to.

Academy of Sciences.

At the meeting of the Academy of Sciences on Monday evening, Vice-President T. J.

**THE NICHOLS ORE BREAKER.**

Evans presided. A. W. Glassford was proposed for resident membership. Quite a large number of donations to the museum were received. These donations consisted of 18 or 20 specimens of sections of native California woods, which had been contributed to the Department of Economic Botany. They were from Towles Bros., of Alta, Placer county, and were donated by Mr. Durgan of the museum of the State Mining Bureau; four globes of crystallized lime from Keokuk, Iowa, donated by Mr. A. Von Schmidt; two specimens of marine life from Ceylon, presented by Mrs. T. H. Hittell; a voracious marine eel, more feared by the divers for coral in the neighborhood of Torres straits than the shark, by the same; a polyp from the bottom of the sea, near Falmouth road in the British channel, presented by Joseph Elfelt; several specimens of elementary coral and marine life from Apia, Samoan island, by United States Consul Greenebaum; an edible worm from the South Pacific islands, spears, bow and arrows, implements of war and the case and insignia of authority made and used by the natives of the New Hebrides islands, by Captain Simpson; other specimens of marine life from different persons. As a number of these articles were from the South Sea islands, a region with which Captain Churchill is familiar, that gentleman gave a very interesting description of the uses to which the various implements are put, and spoke of the customs of islanders in the different groups.

The damage done to the main shaft of the Grand Central mine at Tombstone, A. T., by the recent fire is more serious than was at first supposed.

The Nichols Ore Breaker.

Mr. E. I. Nichols, of this city, has recently patented, and is now manufacturing, a new style of ore breaker and pulverizer, for which many advantages are claimed over machines of like character in the market. It is very compactly built, simple and durable. The jaw is mounted on a revolving eccentric shaft, working against a cylinder or roll in an oscillating motion, which causes the roll to move slowly around with each down stroke of the jaw, but it is prevented from moving back, as the jaw ascends, by small balls, which lay in each end of the roll and against wedge-shaped projections, on the inner face of sides. The lower end of jaw is secured to the shaft of the cylinder by connecting bars. In the end of those bars are heavy set screws for regulating the grade of crushing to be performed. The jaw is provided with a shoe of white metal or steel which can be reversed. The eccentric shaft is fitted with two heavy balance-wheels, tight and loose pulleys. The engraving on this page represents this new machine.

The small machines are made with a lever, and are suitable for assayers and esmples, on account of the ease and rapidity with which they can be cleaned up after pulverizing each lot of ore. Another style of these machines is made with crank and pulley, and is a very desirable article for prospectors on account of the ease with which it can be transported on pack animals. Wet or dry ore can be crushed to

any desired fineness, and will always have a free discharge, the cylinder or roll carrying down the pulverized ore as rapidly as the process of crushing is accomplished. Mr. Nichols claims that any roller, ball or stamp mill can accomplish from 30 to 40 per cent more work by the use of his machine in conjunction as a fine crusher. He claims further that it will accomplish as much work as any roller mill of like capacity with one-third the power necessary to operate the roller mill. The capacity of these machines ranges from 500 pounds to 16 tons a day, according to size.

THE American Association for the Advancement of Science and the New York State Exempt Firemen's Association will meet at Buffalo, N. Y., on August 17th. The city council has appropriated \$5000 for the Fourth of July and the reception of the distinguished visitors. The local scientists have asked for \$2000 of this to help entertain their friends, and the firemen want \$2000. There is now a quarrel to see which shall get the appropriation.

OF THE mining assessments delinquent this month, aggregating \$213,500, Nevada calls for \$144,000, California \$17,500, and Arizona \$52,000. For the same month last year there were the same number of assessments, amounting in the aggregate to \$270,900, of which \$232,000 was claimed by the Nevada mines.

It is stated that the sale has been perfected of Henry's diggings in the eastern part of El Dorado county, a gravel mining claim, for \$30,000. A Chinese firm in San Francisco were the purchasers.

Mining Accidents.

Elijah Hill, a well-known miner of Bingham, Utah, came very near losing his life the other day in the Winnemuck mine. He had just come up from the shaft, and ordered the cage returned to the 100-foot level. The cage was returned and Mr. Hill, forgetting all about the matter, turned in a few minutes and walked into the shaft, falling the distance of 100 feet. He broke both legs and an arm, and it was almost a miracle that he did not lose his life.

Fred Telham, employed in the Prudence mine, Nevada county, while working in one of the stopes was hurt by a large rock which became loosened and fell upon him.

Patrick Mullen was very badly injured in the hoisting works of the Badger mine, Grass Valley, last week. Mullen was working there and having occasion to cross from one side of the building to the other, he attempted to cross over the sweep-hob of the pump. The pump was running at quite a high rate of speed. Mullen waited until the "down stroke" of the hob and then proceeded to cross. He missed his calculation and was not quick enough, for the "up stroke" caught him beyond his balance and threw him violently into the cogs of the wheels running the pump. The rapidity of the revolutions soon drew the victim in, and the wheels began their horrible work. The left foot was chewed off just above the ankle, leaving the foot with the boot upon it on the floor under the machinery. The right leg was badly crushed below the knee, both bones being fractured. The flesh and outer muscles of the left thigh were frightfully torn and mangled, almost exposing the bone of the thigh.

A miner employed in the Clark's Colusa mine, Butte, was killed last week. Shortly after midnight he left his work and went back about 100 feet from the shaft for a drink of water. When he started to return it seemed to occur to him that it would save time if he would take some giant powder back to the face of the drift with him. There was about 11 pounds of giant powder in a box and some boxes of caps, which had been placed at this point to guard against accident while blasting. He was seen to stoop over the box containing the powder and caps, when his miner's candlestick dropped in among the caps and a terrible explosion followed. On going to the place where the explosion occurred it was found that his head had been entirely blown to pieces and that his breast and shoulders were in much the same condition.

About 15 minutes after the occurrence of the above accident Alex. Finlayson, who was working on the 800-foot level of the same mine, was getting ready to put in a set of timbers. His partner was on top getting the material. While clearing away the dirt a lot above caved, striking him on the head, causing a severe scalp wound.

AMONG the most notable mining regions around Spokane falls is the South Fork country. Geographically it is known as the South Fork of the Cœur d'Alene river. Three years ago there was not a prospect hole here. Now there are two thrifty towns, seven prosperous camps, a permanent population of at least 1000 people; while swarming the hills, following old trails or blazing new ones on their way through a terra incognita, there are said to be at present 500 miners.

IN the matter of the Smokehouse lode mining claim at Butte, M. T., the Secretary of the Interior has declined to advise that a suit be instituted in the name of the United States, to set aside the patent issued for said claim. Application was made on behalf of the claimants under the town site location. The case involved a large amount of property rights in Butte City.

COAL is in fair movement, with a scarcity of Seattle, West Hartley and Scotch. There has been no Seattle on the market for a month or two, but renewed supplies are expected soon. Receipts of coal for May were 67,129 tons, making the total since January 1st 290,306 tons, against 382,811 tons for the same period in 1885.

FRANK P. McLAIN, a graduate of the University of California, who has been in the Patent Office for some years, has been promoted to be Chief Examiner in the Metallurgical Division.

MECHANICAL PROGRESS.

Novelties in Locomotive Construction.

One of the recent novelties in locomotive construction in France is to be found in the design of M. Estrade, which he proposes to try on the southern lines in France. M. Estrade has not confined himself to the locomotive, but has also designed a complete system of rolling stock for a passenger train, which has been exhibited in model form at the Conservatoire des Arts et Metiers, and will shortly be put to the practical test. His locomotive is of the outside cylinder type, with slide-valve on the top of cylinder, and all the gear carried outside, according to the general plan on the Continent. He believes in large wheels, and the six wheels of his locomotive are 8½ feet in diameter, coupled and placed as close together as possible.

It is calculated that this engine will be capable of maintaining speeds of 72 to 78 miles an hour. The tender also has wheels 8½ feet in diameter, but otherwise presents no features of novelty.

The coaches are peculiar in that they are carried inside iron girders, while the wheels run under the center of the longitudinal seats, thus admitting of a much larger diameter than those in ordinary use. Two axles, 16 feet apart, support, through elliptic springs mounted upon the oil boxes, these longitudinal girders, which have ends curving toward the ground. Each girder carries three other elliptic springs, from which is suspended, by means of iron rods, the lower frame on which the body of the car is supported. The coach is separated into two stories, the lower of which is made in three pendant sections with doors, which may be used as baggage-rooms, etc. Above is a single compartment with central passageway, reached by stairways at each end of the coach, and communicating with the other portions of the train by hinged platforms.

Another novelty is the compound engine of Mr. Von Borries, which is employed on the Hanoverian section of the Prussian State Railways, and which is especially notable for the starting-valve, which is shut by the driver when he wishes to start, and blocks the passage through the receiver from the high to the low-pressure cylinder. While the valve is in that position steam can flow from the boiler to the low-pressure cylinder through a pipe and connection, in which it is so throttled as to equalize the steam pressure on the larger area of the low-pressure piston. The engine having thus been put into motion, the exhaust from the high-pressure cylinder passes into the receiver, but cannot pass to the other cylinder, because the way is blocked by the starting-valve. The pressure accordingly accumulates in the receiver until it is sufficient to force the starting-valve back against the pressure of the throttled steam supplied direct from the boiler to the other side of the valve, when the engine at once commences to work compound. The starting-valve is, we believe, arranged to work automatically, so that all the driver has to do is to open the regulator in the ordinary way, and the engine will start, as boiler steam is supplied to both cylinders. Compounds of Mr. Von Borries' make have been working for the last five years, and, it is stated, with a fuel economy of from 10 to 20 per cent over engines of the same weight and performing similar duties.

STEAM CUSHIONING IN THE CYLINDER.—The statement has been made by machinists of repute that compressed steam cannot be used for a cushion in the cylinder of a steam engine except at the expense of a portion of the power stored up in the fly-wheel. Against this opinion, it is said, there is a certain amount of power lost in reversing the reciprocating parts of a steam engine, but what we want to know is how to obtain that power with the least expense. Within certain limits compression for that purpose is right. In case we have no compression and the piston is allowed to pass to the end of the stroke perfectly free, we will be compelled either to call upon the fly-wheel to arrest the momentum of the piston and connection, or to give the valve excessive lead. In the former case there would be a loss of power, and in the latter a loss of steam. For instance, take a steam engine 30x36 inches, with piston, cross-head and connecting rod weighing 1300 pounds, and a piston travel of 600 feet per minute. When that 1300 pounds of metal is moving in a straight line at a rate due to the piston travel, we want to stop it at the end of the stroke, and start it back on the return with as little expense as possible. In a well-regulated engine the compression should be just sufficient to bring reciprocating parts to rest independent of any appreciable strain on the crank-pin. The steam which has been forced into the clearance has taken no power from the fly-wheel, but has relieved it of the resistance it otherwise would have met in reversing the heavy parts. A steam engine cannot yield good results without a cushion.—*Iron.*

DRIVING GRINDSTONES.—An improvement in the driving of grindstones and emery wheels is that by which the wheel is given a reciprocating lateral motion in addition to its rotation. Every one has noticed the advantage of moving a tool from side to side on a grindstone so as to equalize the attrition on the different parts of the edge. It has now been found that by making the grindstone move laterally, and

keeping the tool still, a more perfect result is attained, while the detached particles of steel have an opportunity to drop off the grindstone instead of being crushed into it, and the wear of the stone and the heating of the tool are both greatly diminished.

CHIPPING IRON.—We find in a cotemporary monthly journal a very neat engraving showing the correct attitude of a chipper chipping away at his vise. It seems that the hammer must be held by the handle close to its outer extremity, where it tapers toward the end, so that the hammer can be brought into a position close behind the right ear. The chisel is placed at an angle of 45° with the surface of the work, and pointed directly at the left eye, which may be either open or shut, as the hand effectually hides the view of the chisel's edge. With the body erect and the shoulders well thrown back, with a slight inclination of the head, the chipper chips his work so nicely that the marks of the chisel are scarcely discernible, which contrasts greatly with the distortions of our best workmen, who make use of at least 13 different grasps of the chisel in chipping out a medallion. The hammer apparently takes care of itself, and may be seen almost anywhere within reach of his right hand. All parts of the body are in sympathy with every movement of the chisel, and the eye of the workman at all times is intently engaged in taking cognizance of what the cutting edge of his chisel is doing.

STEEL NAILS.—A hardware dealer correspondent of the N. Y. *Iron World* writes in regard to steel nails as follows, from Peoria, Ill.: "Steel nails are not meeting with any favor from the majority of our mechanics and leading contractors, nor am I compelled to keep them in stock to any amount. The objections offered are that in case the steel nail bends in driving or is not properly driven, and necessitates being pulled, it is almost impossible to withdraw it without tearing the board. I have examined the steel nails closely and find they taper from one side to the other very gradually, and this fact causes them to turn, and consequently bend very firm. In nice work the withdrawing of a nail mars or breaks the wood, which is not the case with an iron nail, possibly because it is formed differently. When a nail is driven it is generally intended to hold and remain there, but it is customary for mechanics to use their studding for making temporary scaffolds and afterward knock it apart and use it in the building. As far as security goes, the scaffold is made more safe with the steel nail, but it renders the lumber unfit for use."

THE "DEAD CENTER" is the point in the stroke where the crank and piston rod are in the same right line. To find dead center, turn engine in the direction it runs until crosshead is within a short distance of its limit of motion. Mark guide at end of crosshead shoe. Mark some revolving circular part of engine, as disk crank or fly-wheel, and place one point of a fixed tram in this mark and the other on some fixed object in line. Now turn engine past the center in the direction she runs until end of crosshead shoe passes mark on guide. Turn back till shoe reaches mark. Holding tram still on the fixed object, place other point on selected revolving part and mark as before. Bisect distance between marks on revolving part, and turn engine till point of tram rests on central mark, and the engine is on "dead center."—*Wood and Iron.*

WASTE OF STEAM IN WHISTLING.—A well-posted railway man says that the obligatory tooting of a locomotive on the New York, New Haven & Hartford Railroad in an ordinary day's run involves a waste of steam requiring the consumption of 230 pounds of coal to renew. He estimates the whistling expenses of that particular railway at \$15,000 per year. There is a similar waste in the blowing of the whistles of stationary and steamboat engines. It is a matter worth the serious study of practical railroad men whether they cannot devise a cheaper voice with which to give notice of the approach of trains to stations and grade crossings.

MACHINERY ON TRIAL.—Buyers of machinery on trial, subject to their approval after operation for a stated period, should remember that they can be held legally responsible for the price of the machinery if they fail to signify their rejection of the same within the specified time. Usually there is a well-understood agreement in these matters; but sometimes there is not, and in such cases it is only just that if the machine purchased is not satisfactory the user should notify the seller as soon as the fact becomes apparent.

STRIP ROLLING.—A sharp thing in steel strip rolling has just been accomplished at the Earl of Dudley's Round Oak Works, England. One of the mills produced in a single turn 25 tons 1 cwt. of 1½ inch by 3 w. g. steel strip in lengths of 12 feet 3 inches. Considering the nature of the material and the size of the strip, this make, it is believed, is unprecedented in the annals of strip rolling in England. The blooms were heated in Mr. Smith Casson's gas-heating furnaces.

THE FIRST CHAIN FACTORY in the South is about to be inaugurated in Birmingham, Alabama, for the purpose of supplying the Southern market with trace chains.

SCIENTIFIC PROGRESS.

An Immense Aerolite.

Our readers will recollect an article which appeared in these columns in October last, in which allusion was made to the report that an immense meteor had passed over a portion of Washington county, Penn., on the night of September 14th, and which was described by several who saw it as being "as big as a barn," and that it was seen to fall but a few miles distant. Professor Emerick, of Williams and Mary college, immediately started in search of it, but failed in the effort. About the middle of last month the professor was again called to that region on quite a different errand—in search of a location to bore for oil. While thus engaged he accidentally stumbled upon the undoubted object of his former search, which in its glowing state, while passing through the atmosphere and in near proximity to the earth—about 50 miles—must have appeared to observers nearly under its track, quite as large as an ordinary barn.

It was found near the point where it was supposed to have fallen, on the farm of Frederick Miller, about two miles north of Claysville, Washington county. It was lodged at the base of a hill, and was deeply imbedded in the soil and covered with dry leaves which had blown into the opening. Prof. Emerick says it is the largest aerolite ever discovered in the world, and is considerably heavier than the combined weight of all the aerolites known to have fallen in the United States. It weighs not less than 200 tons, and is composed of chromium, nickel, copper, aluminum, magnesium, and 10.87 per cent of it is iron. He calculates that it was seen in motion for a distance of 150 miles, and moved at the rate of 20 miles a second. It required three men several days to unearth the monster. It had penetrated the earth until it came in contact with a stratum of limestone, when this sudden check of its fearful velocity caused it to break into many pieces of all sizes and shapes; yet when the earth was removed from around it, it still preserved its original shape, so that the professor was enabled to have a photograph made of it, and it only fell to pieces when the specimen-hunters tackled it.

Expansion Produced by Amalgamation.

At a recent meeting of the London Physical Society a paper on "The Expansion Produced by Amalgamation," by Professors Ayrton and Perry, was read. It had been accidentally observed by the authors that the amalgamation of brass is accompanied by great expansive force. If one edge of a straight, thick brass bar be amalgamated, it will be found that in a short time the bar is curved, the amalgamated edge being always convex and the opposite concave. The authors imagine that a similar action may be the primary cause of the phenomena presented by the Japanese "magic mirrors." Japanese mirrors are made of bronze, and have a pattern cast upon the back, and although to the eye no trace of it can be discovered upon the polished reflecting surface, yet when light is reflected by certain of these mirrors on to a screen, the pattern is distinctly visible in the luminous patch formed.

In a paper read before the Royal Society it has been shown that this is due to the polished side opposite the thinner parts of the casting being more convex than the others, a conclusion verified by the fact that the pattern is reversed when formed by a convergent beam of light. Such a condition of things would evidently result from a uniform expansive stress taking place over the reflecting surface, the thinner and consequently the weaker parts becoming more convex or less concave than the others. The authors have hitherto attributed this inequality of curvature to a mechanical distortion to which the mirrors are intentionally submitted during the manufacture, to produce the general convexity of the polished surface, but they now think it possible that the use of a mercury amalgam in the process of polishing may have an effect in the production of this inequality of curvature.

CONDITIONS OF CORROSION.—Speaking on the "Corrosion of Iron and Steel," Mr. T. H. Davis, F. I. C., formerly assistant at the Royal College of Chemistry and School of Mines, London, says if the air or water which surrounds iron contains carbonic acid, or any free acid, in minute quantity, the corrosion increases rapidly; but if a caustic alkali, such as potash, soda or lime, be present, the corrosion ceases altogether while any causticity remains, because oxygen and carbonic acid have greater affinities for these alkalies than for iron. He also points out that a perfect paint for the protection and preservation of iron and steel should be one which has a high mechanical adhesive property, and composed of such materials as are related electro-negatively to iron, mixed with some tenacious fluid vehicle containing little or no oxygen, and not capable of being decomposed by the iron beneath it. This would exclude most oily paints.

ARTIFICIAL AND SUN HEAT.—No explanation has been found of the familiar fact that, while both the light and heat of the sun pass unimpeded through glass, artificial heat is intercepted by this transparent medium. It is

strange that the heat of an ordinary fire should pass freely through a layer of rock salt, when it is unable to penetrate a pane of common glass; and it is worth observing that while the hot rays of the sun pass through glass with such perfect freedom, they cannot find their way back by the same channel. The warmth once inclosed in a hot-house cannot escape by the process that allowed it to enter the building; it must first heat the glass panes in the roof as it would any other substance, in order to get out again.

THE EARTH AS A TIMEKEEPER.—A problem, which is attracting to its study astronomers, relates to the earth as a timekeeper. We measure time by dividing either the period during which the earth revolves around the sun, or that in which it turns on its own axis. By the first method we measure a year; by the second, a day. The earth, according to some astronomers, is losing time. Through two causes—the sun's attraction and the friction, so to speak, of the tides—the earth each year revolves more slowly on its axis. The speculative question which these astronomers are discussing is whether in the end the earth will stop its revolution upon its axis and will present always the same face to the sun. When that event occurs, there will be perpetual day in one part of the earth and perpetual night in another. But there is no occasion for immediate alarm. The rate at which the earth is supposed to lose time only shortens the year by half a second in a century. There are more than 31,500,000 seconds in a year. Therefore, if the earth ever does cease to revolve on its axis, it will be more than 6,000,000,000 years before it will stop.

DISTRIBUTION OF EARTHY MATTER IN PLANTS. Berthelot and Andre have published their second, third and fourth memoirs on the general march of vegetation in an annual plant. They find that the mineral matters which become insoluble by incineration have a marked tendency to accumulate in the leaves. In plants with a languishing vegetation, however, they sometimes seem to be arrested in the roots, probably in consequence of the insufficient action of the agents which render them soluble, and enable them thus to reach the leaves through the circulation of the sap.

A PHENOMENON SELDOM NOTICED.—M. Treve has described to the French Academy of Sciences a phenomenon of a beautiful green ray which he has observed to follow the disappearance, for a quarter of a second after sunset, of the upper limb of the sun's disk. The flash of the ray is as quick as that of lightning, and can be seen only under unusual conditions of clearness of the sky. The author explains the appearance under M. Chevreul's theory of the simultaneous contrast of colors.

THUNDERSTORM IN A CLEAR SKY.—Captain Anderson, of the British bark *Siddartha*, which lately arrived in New York, reported a peculiar thunderstorm on April 27th, while on the northern edge of the Gulf Stream. The sky was quite clear at the time and the sun shining brightly, although there appeared to be a thin mist about the ship. Suddenly there appeared a vivid flash of lightning, accompanied by violent thunder. The compass was caused to vibrate perceptibly for a period of 15 minutes.

CLOUDS DEPENDENT UPON DUST.—Investigation by Dr. R. Von Helmholtz, described to the Berlin Royal Society, confirms the statements that the formation of cloud in saturated air is induced solely by particles of dust, and that the finer and sparser are the dust-particles the more slowly is the cloud formed. These results are also confirmatory of Prof. Tyndall's explanation that the blue color of the sky is due to floating dust.

JUPITER, THE GIANT PLANET, though 1200 times the bulk of the earth, is only 300 times its weight. Its bulk is largely made up of gaseous matter; but whatever that may be, its power for reflection are such that it is known to reflect nearly one-half the light that falls upon it from the sun. Its brightness, by some, however, that a portion of its light comes directly from the planet itself as a self-luminous body.

HEAT OF THE SUN.—In the focus of a burning glass, the sun's rays will melt the most refractory substances. The heat, then, of the sun is most intense. If we were as near to the sun as we are to the moon, the whole solid earth would melt away as wax.

WONDERFUL PROGRESS is being made in microscopical science, the president of the British Microscopical Society recently pointing out that results are now attained which mathematicians five years ago declared to be impossible.

THE HUMMING OF TELEGRAPH WIRES, according to R. W. McBride, is not caused by either the wind or by electricity, as is popularly supposed. It is accompanied by a rapid vibration of the wires and its origin is an unsolved problem.

THE POLAR SEAS.—A German physicist argues that the polar seas must be higher in summer than in winter, when the accumulation of ice increases the saltiness, consequently also the density of the water.

THE CRIMEA.—A thorough scientific examination of the people and prospective resources of the Crimea is to be made by representatives of the Russian Government.

ENGINEERING NOTES.

Railroad Building the Present Year.

It is appropriate at a time when general business depression and labor troubles are uppermost in the minds of most people to look away for a moment at an enterprise which forms an important factor in all business operations, and which regards such troubles with the keenest eye to the future. By so doing we shall learn that that factor is quietly shaping itself for an early return to an increased amount of business in the near future. We refer to the great railway builders of the country. Figures already published by the best authority show that during the first four months of 1886 railroad building in this country has covered twice the number of miles added in 1885. It is also confidently asserted that this comparative increase will hold good throughout the remainder of the year, and that at least 6500 miles of new road will be added to our present grand total before January 1, 1887. Moreover, during the same time the efficiency of our existing roads will be greatly increased by improving the tracks, etc.

Men interested in railroad progress estimate that during the year not less than 3000 or 5000 miles of existing railroad lines will be relaid with steel rails. One million tons of steel rails will be produced during the present year, of which 750,000 tons have already been sold. A million tons of rail will lay 10,000 miles of railroad track.

As a further increase of facilities for transportation, the 30th day of May was employed by the Louisville & Nashville road from Louisville to New Orleans in changing the gauge of the track to that of the standard width. The change in the track simply consisted in moving one rail three inches toward the other. All the inside spikes had been removed as far as possible and the ties prepared for the rail. Four or five men were detailed to each mile of the road and the great work was accomplished between daybreak and 5 p. m. The locomotives and car trucks had been previously reduced to the standard, for the former did not work well, frequently leaving the track and causing several minor casualties. A delay of 12 hours occurred in the Southern mails and freight in consequence of the change of gauge. It was thus that the Louisville & Nashville changed 1300 miles of track, all told, at a cost of about \$500,000.

Railroad building in this State has also taken a new start. The Southern Pacific is actively engaged in extending its track southward from Soledad to make connection with the main road at Newhall. The Los Angeles & Pasadena road is being rapidly extended eastward toward San Bernardino. Extensions and branches are also in contemplation on the San Gabriel portion of the Southern Pacific. Extra depot accommodations are also being made both on that and the Atchison & Topeka road at and near San Bernardino and Colton. The Northern Pacific is also being pushed forward toward Oregon; while it is in contemplation to push the Donahue road still further northward.

AERIAL NAVIGATION.—The French Academy of Science received, at its sitting of the 23d of November, an interesting communication from Captain Renard, on the subject of some experiments made by him with his navigable balloon. The memoir was received with great favor by the Academy, which decided that it should be inserted verbatim in the transactions, although this is contrary to the general practice. The motor employed was a Gramme dynamo-electric machine, developing 9 horse power. The current actuating the machine was furnished by a battery that constitutes the most interesting feature in the installation, but the arrangement of which is kept secret. The experiments have been repeated in the presence of the Minister of War, and it is said there appears little doubt that M. Renard's experiments, so far as they went, were a complete success. The Minister of War has ordered the construction of a much larger balloon for conducting experiments on a more extensive scale. These will take place this year.

RAILWAY MILEAGE IN CANADA.—It appears from statistics, recently published, that there are 10,027 miles of railway in operation in the Dominion of Canada, 2694 of which only are included in the intercolonial continental road. This amount of mileage compares favorably with that of any other country in the world, considering the difference in population and little populated territory through which the route runs. In addition to this extent of road, which is in actual operation, there is a considerable mileage on which track has been laid, and which will be open for traffic in the course of a few months, and there will be, undoubtedly, at least 11,000 miles of railway in operation in Canada by the 1st of July, 1886.

THE PANAMA CANAL was discussed at length in a recent Cabinet council, which finally decided to authorize the Panama Co. to issue a loan of 600,000,000 francs in shares, provided the company are able to prove that this sum is sufficient to complete the canal. The company, on the other hand, have decided to postpone the execution of all work not absolutely indispensable to the opening of the canal to traffic, and thereby fulfill the conditions required by the Government.

USEFUL INFORMATION.

OLD POSTAGE STAMPS.—A Parisian paper has set itself to discover what becomes of the old postage stamps—a question which has vexed the soul of many curious persons on this side of the channel. It was alleged that they were collected for the defrauding of the revenue, the postmarks being obliterated and the stamps reused. Obviously, however, the small scale upon which such a fraud could be conducted would not account for the millions of used stamps which were known to be collected by the convents. It appears that the convents convert their pupils and their pupils' parents into collectors, and when a million stamps have been amassed and sorted into countries and values they are sold to the dealers in foreign stamps, who pay from £14 to £16 per 1,000,000 for them. It is calculated that their retail sale and export to other countries leaves the dealer an average profit of £84 per 1,000,000. Philatelists will be interested in knowing, on the authority of our Parisian contemporary, that the one-franc stamps of the Republic of 1849 are now so scarce that they command about £3 each. It would seem, therefore, that a Frenchman might leave his children a worse heritage than a trunkful of old envelopes.—*St. James' Gazette.*

IMPROVEMENT IN MAKING WOOD PAPER PULP.—A combined chemical and mechanical process for the reduction of wood to fiber consists in first submitting the material to the action of chemicals, the next step being that of grinding. The wood is cut into blocks, much shorter than usual, or transverse saw scars are made at intervals across the ends, so as to aid the solution in permeating the fibers and loosening them. The wood is then put into a strong solution of lime, soda ash, chloride of lime, or other equivalent, and subjected to boiling under steam pressure for 24 hours. After the chemical treatment has been perfected the wood is removed from the tank or boiler, and is then subjected to the action of the grinders in the usual way, keeping a constant stream of water upon the stone. This effects the disintegration with great rapidity, owing to the preliminary treatment received by the blocks, and no washing is required beyond what results from wetting down the stone.

ECONOMIZING IN SUGAR MANUFACTURE.—The utilization in sugar-making countries of the residual caues, bagasse, for fuel and gas-making, is an important practical problem which has yet been only partially solved. The great obstacle has been the large proportion of water which it contains. It is stated, however, that a system has been devised of successfully dealing with the material. This result is obtained by a preliminary division of the pieces of cane in a special apparatus, whereby the after compression of the material by presses of any convenient kind may be usefully secured. The compressed material is formed into bricks by the addition of powdered fuel, ashes or lime. It is cited as a remarkable instance of the utilization of a waste product reacting upon the original value of the material that this conversion of waste sugar-cane into a useful fuel will render possible a special treatment of the cane which will result in simplifying processes, saving labor and increasing the yield of the raw article.

BEDS, NOW AND THEN.—Two hundred years and more ago the beds in England were bags filled with straw or leaves, but not upholstered or squared with modern neatness. The bag could be opened and the litter remade daily. There were few bedrooms in the houses of ancient England. The master and mistress of the Anglo-Saxon house had a chamber, or shed, built against the wall that inclosed the mansion and its dependencies; their daughters had the same. Young men and guests slept in the great hall, which was the only noticeable room in the house, on tables or benches. Woolen coverlets were provided for warmth; poles or hooks on which they could hang their clothes projected from the wall; perches were provided for their hawks. Attendants and servants slept upon the floor.

A CEMENT FOR RESISTING SULPHURIC ACID, even at boiling heat, may be made by melting caoutchouc at a gentle heat, and adding, with constant stirring, from six to eight per cent of tallow. Then mix therewith enough dry slacked lime to make the whole the consistency of soft paste; finally, add thereto about 20 per cent of red lead, whereby the mass immediately sets hard and dry. A solution of caoutchouc in twice its weight of linseed oil, aided by heating, and the addition of an equal weight of pipeclay, yields a plastic mass which will likewise resist most acids.

OIL FROM PINE WOOD is now manufactured on a considerable scale in the South. The material is subjected to intense heat in sealed retorts, and one cord of it is said to yield 15 gallons of turpentine, 80 gallons of pine wood oil, 50 bushels of charcoal, 150 gallons of wood vinegar, and a quantity of inflammable gas and asphaltum.

PAPER CIGAR BOXES.—Attempts have been made in Germany to make cigar boxes out of paper, instead of out of expensive woods, and the result is said to be very satisfactory. They are made waterproof by being covered with a

varnish, and the name of the firm and the quality of the cigars are put on the boxes during the process of manufacture. The advantages of these boxes are that they weigh little, last a long time, and cost little to produce.

HICKORY HANDLES.—A correspondent of the *Scientific American* asks: What will prevent worms from eating hickory handles? Answer: Most solutions adapted for this use are somewhat poisonous, and hence not adapted to handles. Creosoting or immersion in hot solution of carbolic acid, with some pressure after thorough kiln drying, would seem safe, and would be effectual provided it did not deteriorate the fiber of the wood. Linseed oil is recommended. Steaming will not prevent it, but will kill any that have begun operations.

THE UNSUCCESSFUL MEN are for the most part men who have not learned any business. If you find in a shop a mechanic—not a man who knows how to turn a stop-cock under his charge but a man who knows the whole mill—you will find a man who, as a rule, has never lacked employment and good wages.

LIME slaked with a solution of salt in water and then properly thinned with skim milk, from which all the cream has been taken, makes a permanent whitewash for outdoor work, and, it is said, renders the wood incombustible. It is an excellent wash for preserving shingles and for all farm purposes.

TURPENTINE IN WASHING.—A little turpentine in the wash-boiler will make clothes very white, and will often remove incorrigible stains from white goods. A tablespoonful of turpentine to a large boiler, or a teaspoonful to two gallons of water. There is no smell, the boiling preventing it.

TO CLEAN MARBLE, mix quicklime with strong lye, so as to form a mixture having the consistency of cream, and apply immediately with a brush. Let this composition be allowed to remain on a day or two and be then washed off with soap and water.

A HANDY SEWING MACHINE.—A "sewing machine which is held in the hand and worked like a pair of scissors" is made at Bridgeport, Conn., the factory employing 75 people, so says the *Boston Herald*.

DECEIT IN COFFEE.—It is said that 200 patents have been granted for machines to polish low-grade coffee and make it look like the best.

GOOD HEALTH.

Treating Cases of Injury.

Surgeon Valentine, of Brooklyn, N. Y., advises the following modes of treating cases of injury: In the case of one injured, but whose hurt was not positively known, he advised that the first act should be to send for a doctor; the next to loosen all tight articles of clothing on the patient, that the blood might have free course; the third act should be to place the injured person in as comfortable a position as possible, with his head low down if he looked pale or was faint, and finally to sprinkle the face and head with cold water. In ordinary injuries he said the dirt should be washed out of the wound, a wet linen placed on it, and then a bandkerchief or scarf tied about it to stop the flow of blood. In cases of hemorrhage he advised, if the blood flowed slightly, that the cut was not dangerous; that at most a small blood-vessel had been ruptured. But should the dark blood well out in a steady stream it was then evident that a large vein had been opened and that the flow should be stopped by pressure over the wound with the fingers or by some other ready means; but if the blood be of a bright red and spurted out of the wound forcibly and by jerks, an artery had been cut and the danger was great. If the hemorrhage was unimportant—that is, if immediate danger to life from the injury was not apprehended—stop the flow by pressure; but if it could not thus be stopped, bind the trunk of the artery between the heart and the wound and press firmly with the fingers. As, however, the hand soon tires in such cases, the next best thing to do is to put a tourniquet on it. [A young man from the audience was called to the platform and the method of using a handkerchief with a stick or bayonet as a compressor was shown.] Simple and compound fractures were next taken up. A simple fracture, he said, was where the skin was not broken. When a bone was broken the fact could be ascertained by any one whose head was cool and whose nerves were steady. In the first place, the limb was shortened; next, there was an unnatural movement at the seat of fracture; then there were violent pains, and lastly, the ends of the bones grated against each other if the patient were not immediately placed in an easy position. Dislocations were at once seen by the altered appearance of the joint, by the mobility of the loosened bones and by the effort to move the joint causing intense pain. The treatment was to promptly replace the joint, but this could only be safely done by a surgeon.

DIGESTIBILITY OF CHEESE.—Of 18 varieties experimented with, Cheddar was digested in the shortest time (four hours), while unripe skim Swiss cheese required ten hours for solu-

tion. There is no difference in the digestibility of all sorts of hard or soft cheese, but all fat cheeses are dissolved the most rapidly, because, being open by reason of the fat, they are the more readily attacked by the solvent. There is no connection between the digestibility and the percentage of water present in the cheese, but there is some connection with the percentage of fat and the degree of ripeness. From examination of the quantity of nitrogen dissolved, the author concludes that, on account of its great digestibility, cheese is the most nourishing of all foods, meat and eggs excepted.—*Jour. Chemical Society.*

The Ordinary Vest a Poor Lung Protector.

Mr. James Hess makes a very sensible suggestion, it seems to us, in the *Herald of Health*, when he calls attention to the absurdity of our present curious habit of wearing cambric-back vests, while the fronts are of heavy material and sometimes wadded, and urges the propriety of protection for both sides of the lungs. The habit of course has grown from a belief that the outer coat is sufficient protection for the back, while the chest needs warmer covering on account of the coat being open. But it seems a disproof of the reasoning that the first unpleasant sensations of chilliness are the so-called "creepers" running down the spine. Even when the warmest woolen material is selected for a suit, the tailor, unless otherwise ordered, will invariably make the back of the vest of some thin, flimsy material, like cambric or silk, though he may deem it advisable to pad the front with cotton wadding. There is no proper reason why the back of the vest should be made so insufficient. The front may be made uncomfortably thick and still fail to protect the lungs, unless the back is made equally thick and warm. In front they are protected about five times as much as in the back by clothing, ribs, flesh, muscle and fat. In the back, the lungs almost come to the surface, and therefore need more protection. Mr. Hess asserts that it has been his custom for two years past, and that many gentlemen to whom he has mentioned the matter have had their vests made with good, warm backs, and after a winter's trial are quite enthusiastic over the change.

They have passed through the entire winter and spring without once taking cold, which is the best evidence in support of the thick vest-hack proposition that could be adduced.

THE TONGUE IN DISEASE.—One of our medical contemporaries states that the different complaints are indicated by the condition of the tongue, as follows: A white-coated tongue indicates febrile disturbance; a brown moist tongue indicates disordered digestion or overloaded prime viæ; a brown dry tongue indicates depressed vitality, as in typhoid conditions and blood-poisoning; a red moist tongue indicates debility, as from exhausting discharges; a red dry tongue indicates pyrexia, or any inflammatory fever; a "strawberry" tongue with prominent papillæ indicates scarlet fever or rotheln; a red glazed tongue indicates debility, with want of assimilative power of digestion; a tremulous, flabby tongue indicates delirium tremens; hesitancy in protruding the tongue indicates concussion of the brain; protrusion at one side indicates paralysis of the muscles of that side.

REMOVAL OF WARTS.—A correspondent of the *Therapeutic Gazette* announces through its columns the virtues of castor oil in the removal of warts. Constantly applied for from two to four or six weeks each day—that is, once a day—it has not failed in my hands, says the writer, in any case of any size or long standing. The time it takes may try the patience of the user, but if faithfully used they will get their reward in the removal of the wart without leaving any scar. I have used it with some success in other growths, and had benefit enough to merit further trial. It might, he adds, be a success in the removal of certain kinds of cancer, especially scirrhus forms.

FROG'S SKIN ON MAN.—Skin from the back of a frog has been used by Dr. O. Petersen for hastening the healing of wounds. Grafts of the size of the thumb-nail were caused to firmly adhere in two days, and in two days more the pigmentation of the transplanted skin had almost disappeared. The resulting cicatrix is of great softness and elasticity. Some of the London hospitals are now beginning to employ frog's skin as grafts in place of other skin.

BURNT COFFEE FOR WOUNDS.—Dr. Oppler, of Strasburg, has discovered in burnt coffee a new antiseptic dressing for wounds. The action appears to be two-fold; first, that produced by burnt coffee as a form of charcoal, and secondly, that which is due to the pungent aromatic odors, which are fatal to the lower organisms. As coffee is always on hand in military expeditions, it will be especially serviceable as a dressing during war times.

GALVANIC PLASTIC EMERALDING.—M. Kergovat, of Brest, is the inventor. The body is coated with plumbago and placed in a bath of sulphate of copper connected with a battery. The body becomes thus incased in a skin or plate of copper, which entirely prevents decomposition. Over this may be applied a second plating of gold or silver.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

SUTTER CREEK.—Cor. Amador *Ledger*, June 5: The Iowa Company has purchased a 10-stamp mill, at Angels, Calaveras county, and is now engaged in moving it here, to erect it on its claim in place of the five stamps heretofore in operation. The stamps are 750 pounds, with double discharge batteries, and the ten stamps are calculated to crush from 20 to 25 tons per day. The mill is almost new, having been used but about three months. It was formerly used at the Bechtel mine, but was discarded on the erection of a larger mill with heavier stamps. The object of the Iowa men in this purchase is to crush the surface rock and dirt, the same as Mr. Stewart is doing at the Lincoln, with gratifying success. The Canal Company is taking up 700 feet of 15-inch pipe that has been used in conducting water to the Mahoney and Lincoln mines, and laying the same from its ditch near the Kennedy, to intersect the Monterichard ditch, for the purpose of conveying water to the Live Oak mine, near Stony creek, owned by Harris and others. They have just had a two-stamp mill built at Donnelly & Howard's foundry, which will be placed in position in a short time. The Amador Consolidated Company has purchased an air compressor to run the Burleigh drill. It is a large machine, weighing something like five tons.

CLAIMS BONDED.—Reginald W. Petre, a capitalist of Duluth, Minnesota, this week bonded from Mrs. A. J. Sargent the Marlette and Sargent quartz claims at Middle Bar, comprising 2700 feet along the vein. The aggregate amount of the bonds is \$28,000—\$25,000 for the Marlette and \$3000 for the Sargent claim. The term of the bonds is six months. Mr. Petre was here in person attending to the business, but left as soon as the matter was consummated. The short period of the bonds induces the belief that something will speedily be done toward a thorough prospecting of these promising locations.

MISCELLANEOUS.—The Tellurium mill was started again this week. A quantity of pipe, 500 feet, made by Hewitt Bros., was sent to the Live Oak claim, two and a half miles west of Jackson, this week. The ledge in the Gover is said to be from 10 to 14 feet in width. In this vast lode there is a four-foot seam of exceedingly rich quartz, the assay value of which runs up into hundreds of dollars per ton. The mill is being placed in a thorough condition of repair, preparatory to being started on a long career of activity. It is expected to resume work this week. A brick valued at \$4800 was shipped from the South Spring Hill this week, the product of a week's run, exclusive of sulphurets. The tunnel which has been run from the side-hill facing the road has made connection with the shaft. The last dividend of Plymouth Consolidated Mining Company, payable this month, was 25 cents per share. The gravel claim of the Hall boys, near Volcano, has turned out very satisfactorily this season. A cleanup made a few weeks ago, comprising a month's run, realized over \$300; the output of last month is expected to reach at least double that sum. At the St. Julian the mill is idle on account of the breaking of the cam shaft. The tunnel is now in 500 feet, and the air had become so bad as to interfere seriously with the prosecution of work. Improved air-pumping apparatus is now being put in. The Zeile reservoir broke this (Friday) morning, pouring all its contents into the creek, and bringing the mill to a standstill. It will take several days to repair damages.

Calaveras.

SHEEP RANCH.—Calaveras *Citizen*, June 5: "It is the prettiest rock I ever saw," said an experienced miner the other day as he held in his hand a piece of the quartz which had just been taken out of the "Hard Scramble mine" near town. "The beauty of the ore amounts to nothing," explained another; "what we want is gold, no matter what it comes in; whether it is found in glass, petrified wood, quartz or charcoal, so long as we get the metal we are satisfied." The ore at present being found in the above mine is of the finest appearing quality, much resembling the rich ore from the Sheep Ranch mine. It contains much sulphurets, galena, and other metals usually found accompanying gold in quartz. However, not a single color can be obtained by the honor, or any be discerned by the eye. The opening of the ledge is one of the best and affords much encouragement to Mr. Smith, who is doing the work. He says he will run the tunnel to Lava Hill or find something. The tunnel is now in about 325 feet, while everything indicates that there should be a good gold-bearing quartz lode there.

El Dorado.

INDIAN DIGGINGS.—Placerville *Observer*, June 5: A. L. Hale, of Indian Diggings, spent a few days at the county seat the past week. He says the recent cleanup at the Hale & Baughman mine was quite satisfactory. The Chic and Ohio mine, Cosumnes township, will be started up next week by the owners—the Parker brothers. This mine has recently been idle, though it has paid well in the past.

Mono.

THE STANDARD CON.—Bodie *Miner*, June 7: Number of men employed in and about the mine, 45. Ore bodies in mine without special change. Ore shipped to mill for the week, 285 tons. Mill was closed for repairs from midnight of Sunday, May 30th, until 7 A. M. of Tuesday, June 1st, but has since been running steadily. Bullion valued at \$723.23 was shipped on June 2d.

THE MONO.—We shipped to the Bodie mill during the week 150 tons of good ore. There were employed 16 miners, two carmen and one blacksmith's helper, and jointly with Bodie Con. two engineers, one carpenter, one carman, one fireman, one miner, one watchman and one foreman.

THE BODIE.—We are taking out ore from the old incline stopes. There were employed four miners and one blacksmith, and jointly with Mono two engineers, one carpenter, one carman, one fireman, one miner, one watchman and one foreman.

THE CON. PACIFIC.—The drift on the Fortuna vein, between Nos. 1 and 2 ledges, has been advanced six feet. Total length of drift, 84 feet. The vein is looking well in the face of the drift. The winze on the 135-foot level has been sunk during the week five feet. Total depth, 31 feet.

THE BODIE TUNNEL.—The south drift, 300-foot level, advanced nine feet; north drift, 400 level, advanced six feet. The ledges in all the drifts look favorably.

Nevada.

NORTH BLOOMFIELD.—North San Juan *Times*, May 29: While at North Bloomfield we learned from a reliable source that the managers of the North Bloomfield mine had given orders to close down the mine and stop all proceedings of every nature and kind; and while at the Derbec we heard it rumored that the North Bloomfield Company had given orders to turn off the water from the Derbec and De Noon mines. This information was only rumor and did not come from any reliable source. It needs confirmation to warrant its belief. To turn off the water from the Derbec would be a great calamity. It would throw out of employment over 150 laborers, many of whom would go forth without a dollar in their pockets, and it would well-nigh ruin many others who are now eking out an existence in that section of the country. We trust the rumor was not based on anything like fact. The probabilities are that the North Bloomfield Company will get up machinery in the near future to work their ground by the elevating process. This they can do without much expense, but whether it will pay is a question yet to determine. The North Bloomfield people are hopeful, and Micawber-like, are waiting for something to turn up.

DELHI.—Sunday, in company with Mr. E. Spofford, of North Columbia, we made a trip to the Delhi mine, which is situated near the Middle Yuba river, on the north side of Grizzly ridge, about three miles south of Pike City. The road to the mine from Columbia hill is a very good one considering the fact that a person, to reach the mine, must descend to the bottom of Grizzly canyon, then mount to the summit of Grizzly hill and then down again to the mine; the ascent and descent being a thousand feet in a distance of less than four miles. As our readers are pretty well informed as to the mine, it is unnecessary for us to describe it; suffice it to say, it is at the present time crushing some very rich rock obtained from a small vein or lode near the Delhi, named the Puzzler. The Delhi Company are pushing work on the 500-foot level; until that tunnel is completed they will have but little rock to crush for the Delhi lode, as the rock between the 300-foot level and the upper tunnel has petered out.

CROWN POINT MINE.—*Tidings*, June 5: The Crown Point mine has been reported as sold several times, but there is no truth in the report. Mr. Gauthier, owner of the mine, is now in San Francisco, talking business to some parties who are bargaining for the mine. Those parties will be in Grass Valley the latter part of this week, and they will go down in the mine, make a thorough examination of the ledge as stripped, and if they find the property as good as represented they will purchase it.

WASHINGTON TOWNSHIP.—Nevada *Transcript*, June 5: In mining matters there is little to record, except that the Eagle Bird mine continues in a very rich body of quartz in its south drifts on the third and fourth levels. So rich is it in these drifts that it brings the average of the whole mine to something over \$30 per ton. As the expense of mining and milling ranges from \$2.50 to \$2.75 per ton, the margin for dividends will be seen to be quite handsome.

PONY GULCH ITEMS.—Coeur d'Alene *Record*, June 2: R. G. Lang is over from Pony gulch to-day. In conversation with the reporter he spoke glowing terms of the quartz prospects of the gulch, and said that considerable excitement has been occasioned by recent discoveries. Already there has been quite a strife to secure locations. Ingram, Lang & Co. recorded four locations to-day, and a water right that is likely to prove of considerable value. Lately several pieces of marvelously rich gold-bearing quartz have been found. One is said to contain \$46.00. Ward Brothers have ceased hydraulic operations for the season and have commenced cleaning bed-rock. They have a pit stripped fully 200 feet long which it will take them several weeks to clean. Their claim is rich and easily worked, they having reached a point where bedrock is only six feet below the surface. All the gravel prospects well and there is every reason to believe that they will have a big cleanup. Above them Strait & Williams are doing good work and getting good pay. Their ground is also shallow and nearly all the gravel pays well. Occasionally pieces of gold are found containing considerable quartz showing scarcely any indications of wash, the belief being quite general among the miners there that they come from a rich lead near by. Reese Williams, who was lately obliged to lay off a few days on account of an injury received, and spent part of the time in Murray, has returned to work. They have water enough to admit of sluicing operations all summer. Ingram & Co. have their 600-foot flume completed, but the water is too low to admit of piping operations this year. They are well prepared to take advantage of the next high water. Meanwhile they and the parties interested with them will begin the work of developing the McCloud and Columbia leads, two of the most promising quartz prospects of the south side, both of which we have previously described.

MOORE'S FLAT.—Nevada *Transcript*, June 8: At the Metropolitan quartz mine, which is superintended by J. Rodgers, the 10-stamp mill is running daily and the supposition is that the rock is yielding handsomely. If it proves a paying mine, Moore's Flat will be one of the lively towns of the county. Messrs. Vond & Hart are still taking out rich-looking ore from their mine at New York ravine. There is no doubt that the clattering of a 10-stamp mill will be heard there before the year is out. McKillican & Co.'s river quartz mine is still yielding handsomely.

Inyo.

KEYNOT.—*Independent*, June 5: John Anton has leased the Keynot mine, Beveridge district, from M. Lasky. Ten men are now at work in the mine. Before the mine was leased it was worked by tributaries. One of these worked ten tons of ore that yielded \$104.20 a ton; another took out 88 tons of the average value of \$68; and a third worked 28 tons that went \$78 a ton. Forty-seven tons of refuse ore

from the dump yielded \$19.25 a ton when milled. The poorest worked ore from the mine milled \$37 a ton.

ORE SHIPMENTS.—The last shipment of ore from the White hill mine netted Barnes & Kehoe, now the sole owners, \$124 a ton. This is a pretty good margin above expenses. Another shipment is nearly ready. Reube Spear has been at work for some months about a mile and a half from the White hill mine. He will make a shipment of ore in a few days, and has a very good prospect.

San Bernardino.

HOPE SPRINGS DISTRICT.—*Calico Print*, June 5: A. G. Rhodes brought in some specimens from the Black Metal mine, in Hope Springs district, in the southeastern part of Death valley, taken from a quantity of ore that samples 150 ounces to the ton. In the last few weeks the shaft on this mine has been sunk 15 feet deeper, and is now 30 feet in depth, with good ore in sight, the ledge being two feet wide. Owing to the hot weather it will be necessary to suspend work on the mine until fall, when it will be resumed with renewed energy by Mr. Rhodes and his partners, who believe that they have a good mine. Should the Carson & Colorado Railroad be extended southward through the great mineral belt that traverses the northeastern part of San Bernardino county, it would naturally pass within about two miles of the Black Metal mine, and also be the means of rapidly opening up the fine prospects in that district as well as the many others along its line.

Shasta.

BULLYCHOOP.—*Shasta Courier*, June 6: This district, which lies partly in this county and partly in Trinity, is coming to the front pretty lively as a quartz mining camp. One mill is now running there, and turning out bullion, and two other mills will be in operation in the near future. The miners of that district have long labored under difficulties that would have disheartened any people except California miners. In the mountain wilderness, and no mode of ingress or egress except trails that would make a Rocky Mountain sheep hesitate to travel, the persevering men of that camp held on to their mines and resolutely kept their faith pinned on Mount Bullychoop. Finally capital came to their aid; Captain Potts and Senator Charles Foster, owning mines there, built a wagon road from Sunny Hill district to the Mount, and by this enterprise, machinery and supplies could be brought in with facility. Activity and life pervades the district, and the numerous and almost inexhaustible lodes are greatly enhanced in value. The Bullychoop, Sunny Hill and South Fork districts are naturally tributary to Anderson and Cottonwood as railroad shipping stations, and these towns will now feel the exhilarating effects of the new era which has come like a benison upon the miners and mine-owners of western and southwestern Shasta.

Sierra.

HOW IT IS TURNING OUT.—*Tribune*, June 5: T. H. Smith is striking it rich in his quartz ledge at Alleghany. He has several men at work pushing ahead developments, and by crushing ore in a hard mortar secures enough gold right along to more than make both ends meet. Last week Smith was at the county seat negotiating with the foundrymen for a Forbes crusher. When that mill is put at work grinding up the ore our friend will have more gold than he can conveniently handle. We are reminded, by the way, how short a distance a man can see underground, and how a life-long miner may sometimes be at fault in his opinion concerning quartz ledges. This same claim which Mr. Smith is now clearly demonstrating to be of value, lay for years without anybody taking the trouble to locate it, much less doing any work on it. When the present owner did go and post a notice and begin work where it had been abandoned years before, many old miners smiled incredulously, and remarked to one another that the "fool-killer" had work yet to do. Smith did not get discouraged, however, despite the opinions of others, and, single-handed and alone, kept hammering away on his tunnel with as much spirit as though every man in the country had assured him that a ledge of solid gold would be the reward of his efforts. The result has not quite equalled that, but still, Mr. Smith has sufficient reason to congratulate himself that he depended entirely upon his own judgment.

WILL HAVE A GOOD MINE.—Thomas Bessler came down Monday from Butcher Ranch. He reported that the work of driving ahead on the True Blue was progressing favorably and that the vein prospects better every day. The boys are confident of opening up a good mine there, and according to all accounts we believe they will.

SIERRA CITY.—*Sierra Tribune*, June 5: Mining operations are becoming more active in this district every day, and the industry was certainly never more promising than now. Everything indicates that the most sanguine hopes of our people will be fully realized. Already this district can be classed among the richest and most prosperous quartz-mining sections of the coast. Below will be found the latest mining news: At the Young America mine the carpenters are busily engaged on the work of adding another ten stamps to the present 20-stamp mill. As soon as these are ready for operation still another ten stamps will be added to the plant—making 40 stamps in all. There is enough ore now in sight in the mine to keep that number of stamps crushing for years to come. At the True Blue claim the tunnel has been run in on the vein 120 feet. In the face of the tunnel the ledge is 5 feet wide and shows a fine character of gold. This claim is on Butcher ranch ridge and the company which owns it was recently incorporated. In the Phoenix tunnel a change in the character of the ground has been encountered within the last few days, and the rock is becoming somewhat mineralized. It is expected that the ledge will be reached the latter part of this month. A party informs us that a few days ago A. Bates and Tom Williams located a quartz ledge in Lady's canyon, about one mile above the Downieville road, which is considered an important discovery. The vein runs northwest and southeast, is from 4 to 6 feet in width in the croppings, and has been traced by the locators for a distance of 4500 feet. The gentleman who gave us this information prospected some of the rock and found it very rich in free gold. The raise of 108 feet from the tunnel to the surface, at the Mercer & Celina quartz claim, was completed

a few days ago. Fine prospects were encountered in the raise. The tunnel at the Brandy City mine has been run 1350 feet up to last week. A raise (for air and drifting purposes) is to be put through to the surface, a distance of 200 feet. Not a Chinaman in any capacity is now employed at this mine. Many other mine-owners at adjacent camps would be doing the right thing if they would follow brother Lawrence's example in that respect. The Rocky Peak Gravel Company, whose claim is located in the Brandy City district, is about to let a contract for running 200 feet of tunnel. They have already run 500 or 600 feet into the hill, and we understand have encountered some very flattering prospects. P. R. Gardner was up from Downieville, Monday, and paid this office a friendly visit. Mr. G. did not have anything very startling to report from the seat of war. He did state, however, that himself and partners had not taken any bullion this winter from their quartz ledge at Poker Flat. Mr. Sutherland, who is interested in the Lindsay claim, at the same camp, is below, endeavoring to raise some money for a working capital. His plan is to erect a stamp mill, providing he can muster the necessary "wind." A 20-foot-high rock dam is being built at the upper Sardine lake by the Young America Company. The structure is a fine piece of engineering skill, and when completed will back up an immense body of water in the lake. Neither expense nor care is being spared in making the dam as solid as the earth itself. T. Berger will very shortly resume operations at his quartz claim.

Tuolumne.

SOULSBY.—*Independent*, June 5: The rich chute of ore struck in the Soulsby mine is increasing in width, having already widened from 8 to 15 inches. It is so rich that those interested say they "could not wish it better." The Soulsbyville people feel jubilant over the big strike, which means good times for everybody there.

THE HYDE MINE.—This mine was last week visited by the San Francisco parties who hold it under contract of sale with the owner, and are working it with vigor and determination to fully develop it. The mine has lately shown such improvement that a mill will soon be placed on it.

NEVADA.

Washoe District.

HALE AND NORCROSS.—*Enterprise*, June 5: On the 2900 level the main lateral drift northward has reached within 100 feet of the Savage south line, and its face is in strongly mineralized quartz and vein matter. A crosscut (No. 6) will be started west from it to-day or to-morrow to explore the ore vein which lies west of the lateral drift. Nothing is being done in the explorations above the 3100 level at present. The drift south from the bottom of the deep winze on the 3200 level is now in 75 feet, following along the east wall of the ore vein toward the Combination shaft.

CHOLLAR.—Good work continues to be done sinking the Combination shaft deeper, and it has now attained the depth of 3222 feet, surpassing in that respect all other vertical mining shafts in the world. The bottom is in vein matter, quartz, porphyry and clay, showing no particular change since last week's report and no increase of water. As soon as sufficient depth is attained for a sump a station will be opened at the 3200 level for a lateral drift north to connect with the bottom of the Hale and Norcross deep winze on that level.

POTOSI.—Diamond drill hole No. 4, on the 3100 level, penetrated east 175 feet, and was discontinued. It passed through about 80 feet of solid quartz. The drillings showed not only strong silver mineralization but a considerable amount of iron sulphurets. Some water came from it, therefore after the drill was withdrawn the hole was securely plugged. Another drill hole is to be started to-day about 75 feet further north, the ground being apparently dryer in that direction.

SIERRA NEVADA.—West crosscut No. 2, on the 520 level, had 15 feet added to its length, making a total of 584 feet. Its face is still in barren quartzite and porphyry, with a little water. It will be advanced no further west at present. Two lateral drifts north and south have been started from it at an eligible point in the vein matter 170 feet from the main north lateral drift. Each of these drifts is now in 23 feet.

CON. CALIFORNIA AND VIRGINIA.—Daily yield, about 400 tons from the various working levels on the 1780 up to the 1200. This ore is all low grade, averaging according to battery samples at the mills, about \$13.50 per ton. A station has been cut out at the C. and C. shaft on the 1400 level and a drain cut throughout the floor of the drift, preparatory to taking out ore through it from that level.

BEST AND BELCHER.—During the week the water has been reduced 23 feet in the shaft, and only 26 feet more remains to be reduced in order to reach the track floor of the 2319 or bottom level. The drainage of this level will be necessarily slow, owing to the drifts being full of water as well as the shaft. As before stated, this bottom level corresponds with the 2500 level of the C. and C. shaft.

SAVAGE.—The main south lateral drift on the 600 level from the Gould and Curry mine is now in 140 feet, and a crosscut east has been started from it to explore the vein in that direction. Thus far the material passed through on this level has been of a character very favorable for the finding of good pay ore.

GOULD AND CURRY.—On the 500 level the west crosscut from the upraise is now in 60 feet, 34 feet having been added during the week. It is all the way in low-grade quartz. An incline has been started from the head of the upraise on this level, which is now up 30 feet on the slope.

YELLOW JACKET.—The old ore stopes and breasts hold out well and yield their regular 140 tons of ore per day, keeping the Brunswick mill running to its full capacity.

ALTA.—The main lateral drift north on the 700 level has not yet reached connection with the old Lady Washington workings, but is expected to do so during the coming week.

MONTE CRISTO.—The main west drift on the 150 level from the new shaft is still advancing. The ground works more favorably.

CROWN POINT AND BELCHER.—About 380 tons

continues to be the daily output of ore from the old workings, from the 1750 level upward.

KENTUCKY.—Daily yield, 60 tons of low-grade ore from the old workings from the 1300 level up.

Columbus District.

HOLMES.—*True Fissure*, June 5: In the ninth level, about 100 feet west of the copper stope, in the crosscut, we have a fine development. This development is now called the Murphy ledge. It is north of the main ninth and west of the copper stope. At this point we have a large amount of unprospected country. When we first cut this ledge we got some very high assays, but they were from small bunches and did not amount to anything except to give us confidence in the ledge. After running east in the ledge a distance of 25 feet we started a raise on a small streak of good ore. This streak has developed into a fine ledge. It is now three feet wide and the average assays from it are \$60 per ton. This is a ledge that has never been cut in any of the upper levels of the mine. The sulphuret winze is producing well, but it is not quite as large as it has been. The hot stope looks exceedingly well. It is improving rapidly and the ore is high grade. The rock around it is hard and progress is slow. The stope below the west drift on the fifth level is giving some \$70 ore. The intermediate stopes between the fourth and fifth levels are looking about the same and giving considerable ore of fair grade. The west drift on the fourth level shows about 15 inches of \$50 ore where we are stopping. The intermediate stope below the east drift on the third level is looking well, and turning out some \$80 ore. A small amount of \$100 ore is being taken from above the east drift on the third level. The east stope on the second level shows a good bunch of \$60 ore. The stopes above the second level are looking about the same and yielding considerable ore. Bullion shipment May 26th, \$10,168.68.

Eureka District.

A PROMISING DISCOVERY.—*Eureka Sentinel*, May 29: Word was received in town last night that a strike of considerable importance had just been made in the Alexandria mine, on Prospect mountain. It appears that at a certain point on the 200-foot level good ore had been discovered and taken out to quite a depth. This was several months ago. It was deemed advisable by the management to run a drift underneath the body from the 300-foot station. A survey was accordingly made by Surveyor Parry, and yesterday evening the interesting ground was tapped and ore of even a better quality than that above was discovered. Unless the management is very much mistaken, it has a body of at least 100 feet in depth of good smelting ore.

ORE SHIPMENTS.—*Eureka Sentinel*, June 5: During the past week ore shipments were made from the mines of the district to the two reduction works in town as follows: To the Eureka Con. works—Rescue mine, 30 tons; Summit, 9; Lawson, 1; Reville, 2; Silver Lick, 28½; Lone Pine, 2½; Paul, ½; Jackson, 22; Silver West, 2½; Dunderberg, 10; Lord Byron, 9. To the Richmond works: Albion mine, 2 tons; Altoona, 11; Macon City, 2½; Dehman, 1; Bullwhacker, 25; Continental, 4; Grant, 8; Prospect Mountain Tunnel, 25; Eureka Star, 2; Williams, 50; Copp, 1; Union and Charleston, 2; Hamburg, 50.

Monnt Hope District.

ASSAYS.—*Eureka Sentinel*, June 2: Hon. Thos. Wren had some more assays made yesterday of ore that he brought in from his Mt. Hope mines Thursday evening. He was especially interested in the assay of one sample, inasmuch as he has considerable of the ore in sight in the mine and a number of tons of it on the dump. It is heavy in lead and went \$30 a ton in silver. If there is anything at all in indications, large shipments can be looked for from Mt. Hope this summer and fall.

Reese River District.

AT AUSTIN.—*Virginia Enterprise*, June 3: The Manhattan mill, at Austin, will start up for another run shortly. The dumps of the tributaries, as well as those of the company, have become pretty well filled, and in the various stopes and breasts of the mines good working openings are made, insuring a good run of the mill for some months. And be it understood that this is no low-grade ore proposition, but, like all similar runs of that mill, it means a yield of from \$200 to \$1000 or more per ton. The other veins are small but exceedingly rich in that locality. The above information is from well-known mining gentlemen of Austin, who are in on a brief business visit to the Comstock.

Silver Peak District.

TO BE REOPENED.—*Walker Lake Bulletin*, June 4: The valuable Silver Peak mines will soon be reopened on a large scale. Those rich ores can be handled profitably since methods have been improved and transportation has been cheapened. Many years ago, when it cost a fortune to haul a load of supplies to those mines, they were worked extensively; but although the ores were very rich the expense of mining and reduction consumed the profit. As the conditions are now changed in all respects as to cost, the result of the present renewed venture may be predicted as highly successful. The ores of the section are both rich and plentiful, and with everything connected with their extraction and working made cheaper and easier, the company, which is taking the mines in hand, undoubtedly has before it a wide margin of profit. Mr. R. B. Catherwood, President of the New York and Silver Peak and New York and Palmetto Mining Companies, is now here and is urging affairs to as early a resumption as possible.

AT WORK.—*True Fissure*, June 5: John Chiatovich, of Silver Peak, was in town Thursday. He says that there are about 20 men at work in the Drinkwater tunnel, which is being run to connect with ore found in the Sentinel mine. As soon as the connection is made the work of developing the mine will be begun this tunnel will make the development work in nearly all of the mines at the Peak comparatively easy.

Pioche District.

FAVORABLE PROSPECT.—*Salt Lake Democrat*, June 3: There is a favorable prospect for the town of Pioche, near the Utah line in Nevada, again blooming forth into something like its former importance and glory. Mr. W. S. Godbe, of this

city, has purchased the once celebrated Raymond & Ely and Meadow Valley mines, which have been consolidated under the one incorporation, and which will be jointly worked in the near future. These properties have been lying idle for years. The Meadow Valley became involved in law, which caused it to close down, and the stoppage of its pumps forced the suspension of operations in the Raymond & Ely, which is an adjoining claim. Both at one time were the greatest bullion-producers in the State of Nevada, and at the time of their closing down the prospects were decidedly favorable in each for developments which would restore them to their former standing. There is a large amount of unprospected ground at and above the depth of the lowest workings, and any blast or stroke of the pick is liable to expose such a body of ore as in the flush times gave these mines and the district a world-wide reputation. We understand from reliable sources that active operations will be commenced at an early date, and upon a scale which will insure the most thorough development of the resources of the property. After all these years of inactivity it will be gratifying to note the booming up again of the old camp into something like its former proportions and importance. This is likely to occur, and through Utah perseverance and enterprise.

ALASKA.

MINING OPERATIONS.—*Alaskan*, May 22: The weather we have been having is unprecedented in Alaska, and old residents declare that never in their experience have they seen such a spring in this country as the present one. Snow falling the 20th of May is something unheard of in this "land of the midnight sun," and we are inclined to believe that in the mountains there is more snow to-day on the ground than there was on the first day of April. This state of things greatly retards mining operations of all kinds in all parts of the Territory—it must very greatly delay the prospectors who have started and those who anticipate starting for the Yukon country. It has delayed the work on the claims at the head of Silver Bay at least two months. In spite, however, of all obstacles and difficulties with which they have had to contend, the Lake Mountain Mining Company is progressing with its work very satisfactorily and is developing its properties as rapidly as could be expected under the adverse circumstances. Mr. Fuller, the manager, spent a day or two at the Lucky Chance the first part of this week, and informs us that he now has most of his material on the ground, that he has no difficulty in obtaining all the Indian labor that he desires and that they do their work to his entire satisfaction. He expected to be able to wash the placer ground by this time, but says on account of the unusual amount of snow it will be the middle of July before the water can be turned on. The pipes are now being made, and if the snow will let up he thinks his prediction of the time will not be far out of the way. It is difficult to believe, but nevertheless it is a fact, that the snow in the mountains is now from 10 to 15 feet deep, while in the gulches and canyons it can be found varying from 25 to 60 feet in depth. While such a condition of affairs has never been known before, the hope and probability is that it will never occur again. The first blast in the tunnel of the Lucky Chance was fired May 7th, since which time the men have been steadily at work, and have driven the tunnel 15 feet in eight days; men are also at work in the shaft. The moment the weather will permit the company will put men to developing the other ledges which belong to its proprietors, and the confident belief of the manager is that they will be found to be as rich as the Lucky Chance. In fact the Nichol Lode is an extension of the last-named ledge. The developments at the head of Silver Bay prove, beyond doubt, the richness of the quartz veins in that district, and demonstrate the fact that mining interests on this island are in their infancy as yet.

ARIZONA.

WEAVER DISTRICT.—*Prescott Courier*, June 3: Col. H. A. Bigelow and Mr. J. A. Park arrived recently from Weaver mining district. The Colonel says there are in the district about 80 miners, a majority of whom are Mexicans. Water is becoming scarce. The dry washing machine has a capacity of 10 or 11 tons per day. It is at work all the time on gravel that pays from three to ten cents to the pan. It is a slow and costly mode of getting out gold, and people down there hope that the Bates or some other company will hurry up and bring in water to wash the rich gravel, of which there are thousands of acres.

SIGNAL.—*Cor. Prescott Courier*, June 3: The Peabody mill closes down to-morrow to enable workmen to place in the concentrators and other additions to the mill. This may require seven or eight days, and then the mill will resume its steady output of bullion. John Colyer is the superintendent of the mill, and his energetic way of pushing work, aided by a good crew of men, will make the delay for repairs very short. Several mining men from California and other parts have been visiting Signal in the last few days. Some of them have visited the new strike and declare it to be a big thing. Mr. Riley, of this place, staked two men to go out to the new strike some four weeks ago. One of the party came in here on the 22d inst. after Riley, claiming that they have found property adjoining the Black Metal mine that was equally as good as it is. If this is so, our little place here is fortunate in owning such a citizen—the locator of the biggest silver strike made for a long time in any place or country. I would say, now, that it is useless for men of no means to go there for the reason that there are more men there than there is work, and the weather is so extremely hot that but little work and no prospecting can be done. The distance from here is about 45 miles west, and many men who could not obtain employment at this place have gone to the new camp to add themselves to a large number of broke men already out there. Those who have employment in your county had better remain there and not quit a situation to hunt one out this way, for work is not easily obtained now, and when it is found the wages are very low.

COLORADO.

CRESTED BUTTE.—*Elk Mt. Pilot*, June 3: We do not set ourselves up to be a prophet, but unless

we miss our prediction very bad there will be greater activity in mining circles here before fall than ever before known. You would like to know in what particular locality the revival will be. According to our judgment we believe the belt of mineral about four miles west of Crested Butte, running in a northeasterly and southwesterly direction, beginning at what is known as the iron swamp, will be the locality. This will take in Redwell Basin and Evans Basin, where the old man Meagher is located. Recently claims have been located in the iron swamp by A. M. Donaldson and John J. McKay. There has been some ore shipped to the Tomitichi Valley Smelting Works, and while it does not run much in silver it is just the kind of iron ore they want for fluxing. We believe that shipments will continue. Farther up the hill from the iron swamp is the Keystone tunnel, worked by Mr. Williams for a Philadelphia company. Fred Krueger came in from Denver last Tuesday and will remain some time, with a view of working his property on Ruhy Hill. He is very anxious to get up there, for while prospecting around the Eureka ground last fall he discovered an entirely new vein which he considers a good thing.

IDAHO.

CLAYTON.—*Idaho Messenger*, June 1: Clayton is the only place in the mountains, north of the Salmon range, that has the look of coming life about it. Of course, all towns in this range are a bit quiet in winter; but as summer comes they usually revive. This year, however, the outlook is not cheerful in any place excepting here. The Smelter started to-day, and we may say everything opens favorably. Ore is coming from all directions, and strange as it may seem to all old residents, quite quantities, aside from Excelsior ore, come right from the town of Bayhorse. This does not argue well for the whole country. Ore should be reduced at the most convenient point to where there are reduction works. Carrying it even one extra mile for reduction is that much loss, but the loss is far greater when it comes to carrying it 15 or 20 miles away from its natural point. All this should and will, undoubtedly, in time, be remedied. Extra work is not like fire or flood, but, nevertheless, it is a loss, and is to be deplored in a country where labor is as expensive as here and capital as limited. The Clayton smelting company have a large amount of coal on hand, therefore there will be little burning at present. No more will be needed for two months, when a large quantity will be required for one stack, as immense amounts of ore are to be reduced. We think the different kinds of business will be prosperous here this season. One can see and feel the good time coming. We visited the Ella mine to-day. It is a large vein of iron and carries a small amount of silver—formerly a great deal more. No place to this mine now shows rich, but its ore is used by the company for a flux. There is a little silver in all. It was considered to be a very valuable property in the early days of this camp. Its walls are lime and as far as we examined it nearly vertical, running about north and south. The company have put three men on this mine of late. Men come in and are put to work in an hour; but laborers must remember that there is only one stack, and that, therefore, everybody cannot come here and get work. It is the only place where men have been given employment so far this season in all our range; but this will not be the rule, we trust, in a few weeks.

MONTANA.

WOODVILLE.—*Cor. Butte Miner*, June 3: Mr. Henry Nickels and brother, in company with seven other gentlemen, including three mining experts and your correspondent, on Sunday last visited the Major Budd mining district. We were met by the superintendent, Mr. Henry McClosky, M. G. Stephen, Farnum & Co., the lessees, and several of the 15 employees. The tunnel has been run in 925 feet. Only last week the teams were withdrawn from delivery of ore. A "horse" was struck on the vein which proved 85 feet in length. From the face, now six and a half feet in width, the party picked down an amount of ore which was taken to the assay office, dried and pulped. The assay resulted in a very large "button," which represented 486 ounces in silver and \$52 in gold. The dump of this mine shows over 150 tons of good ore. The ore at present being extracted is sacked in the face, and so carried out on the car. Contingent to these mines, and adjacent, are those owned by Col. H. H. Horst, namely: The Silver King, Bonanza, Argenta, Cleopatra, Hannibal, Sierra Madre and Crown Point. This group of mines has been bonded to a California company for \$250,000. In less than two weeks hoisting machinery will be on the ground, and sinking will be commenced on a new shaft. The district not only promises well, but looks well as far as the mines are concerned. The veins are of good width, and carry a sufficiency of ore to warrant the owners in working them. The Otranto mine has on it a 35-foot tunnel and 15-foot shaft. The owners are drifting on the vein 500 feet. Seven feet of ore is worked on in the tunnel. Spurs and angles are continually coming in. A picked sample, assayed a few days since, showed 1375 ounces in silver and a trace of gold, but the general run of ore will not go over \$30 to the ton.

GLOSTER.—*Cor. Helena Independent*, June 5: Happening to be in the camp of Gloster recently, I met John A. Stemple, the father of this district, or the first man who ever prospected for or found quartz in this section. He tells me he has struck it enormously rich in the Piegan lead, one of his finds, and the same vein as the famed Gloster. Mr. Stemple says he can make good wages with a hand mortar. Mr. J. Gould showed me some of the quartz, and he says it pans over \$1000 per ton and there is at least four feet of it. Dorrity and Treddell are running a prospect tunnel in the Gloster hill for the purpose of cutting the old Parole and Zulu lodes, which prospect well on the surface. Another rich body of gold quartz is reported to have been struck on the Penobscot and Snow Drift ground. The Cruse mountain lower tunnel is now in nearly 300 feet, and they should soon encounter the huge body of ore that shows up so plentifully on the surface workings. A day and night shift are crowding ahead the south Drum Lummon tunnel, which by fall should bring the heading into the south Drum Lummon or Nine Hour vein where it crosses their ground. By this time the Bald Butte ten stamps are waking the echoes. I am told the B. B. mines im-

NEW MEXICO.

KINGSTON.—*Socorro Bulletin*, June 5: As an evidence of the opportunities afforded in this camp to miners of moderate means, we cite the fact that Rentschler & Canfield secured a six months' lease on the Comstock mine. For half of that period they worked the property indefatigably, and on Saturday, the 8th, succeeded in striking the present ore body, which is the marvel and pride of the district. From that date until the 20th of May, when our representative visited Kingston, they had taken out on an average \$12,000 per day, of which one third goes to Barton and Rugg, leaving \$4000 apiece for the fortunate lessees. The mineral is shipped by Rentschler & Canfield to Socorro for treatment. Kingston affords lead as a galena, as a carbonate and as a sulphate; silver in the form of chloride, sulphide and in some instances in a metallic state; copper occurs as a blue and green carbonate, as well as argenticiferous gray copper. In some cases the amount of silver contained reaches \$2000 per ton. One of the great wants of the camp is a sufficiency of teams to haul the minerals to Lake valley, the terminus of the A. T. & S. F. branch, distant 30 miles. Shippers are paying from six to seven dollars per ton for transportation this distance. G. W. Holt has leased his Savage claim to Campbell & Murray, who are cross-cutting at present, and have in view a big bonanza when they reach the deposit. Judge Holt is also developing his Eclipse, General Jackson and Uncle Jack, all of which are yielding pay lead mineral, carrying silver. Among the shipping mines of this camp our representative secured the names of the following: Virginia, Comstock, Gallico, Lady Franklin, Gray Eagle, Superior, Temple, Black Colt, Keystone, Illinois, Caledonia, Brush-hap, Louisville, Iron King, Blackeyed Susan, Bullion and Dimmick. The principal features of this camp are the small amount of capital used in the development of the properties, the energy of the miners who, under the great disadvantages of Indian incursions and the want of capital, have succeeded in placing Kingston in the front rank of silver producers. The strike in the Comstock is the prevailing topic in the camp. On the 20th inst., a 15-foot breast of ore was exhibited, and since then it is said to have enlarged considerably. This property produces ore running all the way from \$50 to \$3000 per ton.

OREGON.

PINE CREEK.—*Cor. Redback Democrat*, June 2: From Mr. G. W. Dresslar, a mining expert from Salt Lake, who has been in the Pine creek district for the past three weeks, we learn the following: Tom Fitch and partner are down on their mine about 130 feet and have struck a very rich vein of silver. The superintendent of the Whitman would not allow anybody to go inside of the mine, so consequently nothing can be said of it. Mr. Dresslar says he likes the Sparta country very well, but when he arrived at Hogum he was delighted with the outlook there, and, as he is agent for a large company, he shipped some of the ore from this place to them, and he thinks after they have tested the rock they will make a purchase, and at once put in a 100-stamp mill that is now lying idle in Arizona. Mr. Dresslar returned to this city Friday, and before his return to Salt Lake he intends to visit the Pocahontas and Granite creek districts. He will remain in the city until he hears from Salt Lake in regard to the Hogum ore.

UTAH.

REVIEW.—*Salt Lake Tribune*, June 4: The receipts of bullion in this city, excluding all ore shipments or sales, for the five months of 1886, were \$2,162,206.89. The product of the Ontario for the same five months has been \$769,578.40, out of which \$375,000 has been paid in regular monthly dividends of \$75,000 each. For the month of May the Ontario product was \$1,678.17 ounces of fine bullion, and \$65,242.24 from ore sales; a total of \$146,920.41. The product of the Daly (mill running but three months, beginning near March 1st) for the five months has been \$228,837.52. For May the Daly produced 37,471.80 ounces of fine bullion and \$19,637.97 ore sales, a total of \$57,109.77. For the week ending June 2d, inclusive, the receipts of bullion in this city amounted to \$90,969.36; of ore, \$86,686.56, a total of \$177,655.92—again a very heavy week in ore receipts. For the previous week the receipts of bullion were \$45,700.62; of ore, \$69,265.44, a total of \$114,966.06. The ore is coming down from the hills rapidly, to rid the mines of the accumulations made during the time of impassable roads, and to supply the shortage of the smelters. The output of the Ontario for the week was 27,318.39 ounces in fine bars, and \$16,916.35 from ore sales. The Daly produced during the week eight fine bars, \$937,622; ore sales, \$16,393.20; total value, \$25,769.42. Base bullion received during the week was valued at \$14,200; silver bars \$14,840. The Hannauer smelter turned out during the week \$23,989 in bullion; the Germania, nine cars, \$20,875; the Pascoe, \$1530. Ore receipts were, by Wells, Fargo & Co., \$38,800; McCormick & Co., (including \$2660 Queen of the Hills) \$29,570; T. R. Jones & Co., \$19,519.39; Union National Bank (6¼ tons Bannock ore) \$2797.17.

SILVER REEF.—*Cor. Pioche Record*, June 5: Mining matters are rather quiet in the Reef at present. The Stormont and Christy Companies are making their regular shipments, and from all accounts they are still good-paying properties. There are rumors of the Christy Company changing hands, but they seem to be unfounded. The Silver Gate mine, owned by Messrs. Bales, Harding & Holling, has every indication of being a first-class paying property. The owners have already shipped about 50 tons of good ore to the leaching works, and have lots more in sight, having a four-foot vein averaging 68 ounces to the ton, and about six inches going 1000 to the ton. There are numerous chlorides not working on company grounds that are holding their ore until the rolls are in operation at the leaching works, where they expect to get better terms than at the company mills.

1850. 1885.
RANKIN, BRAYTON & CO.,
...BUILDERS OF...
MINING MACHINERY.

San Francisco: 127 First Street. Chicago: 100 N. Clinton. New York: 145 Broadway.

PLANTS FOR GOLD AND SILVER MILLS, embracing machinery of LATEST DESIGN and MOST IMPROVED construction. We offer our customers the BEST RESULTS OF 35 YEARS' EXPERIENCE in this SPECIAL LINE of work, and are PREPARED to furnish from SAN FRANCISCO or CHICAGO, the MOST APPROVED character of MINING AND REDUCTION MACHINERY, adapted to all grades of ores and SUPERIOR to that of any other make, at the LOWEST POSSIBLE PRICES.

We are also prepared to CONSTRUCT and DELIVER in COMPLETE RUNNING ORDER, in any locality, MILLS, CONCENTRATION WORKS, WATER JACKET SMELTING FURNACES, HOISTING WORKS, PUMPING MACHINERY, ETC., ETC., of any DESIRED CAPACITY.

WATER JACKET SMELTING FURNACES

For COPPER and ARGENTIFEROUS LEAD ores of NEW and ORIGINAL DESIGNS, covered by LETTERS PATENT. No other Furnace CAN COMPARE with these for DURABILITY, and in CAPACITY for uninterrupted work. MORE THAN 150 of them are now RUNNING in various parts of THIS COUNTRY, as well as many in FOREIGN COUNTRIES, giving results NEVER BEFORE ATTAINED as regards CONTINUOUS running, ECONOMY of fuel, AMOUNT and QUALITY of BULLION produced. These CLAIMS have been PROVEN BY RESULTS in ANY NUMBER of INSTANCES, and the GREAT SUPERIORITY of this SYSTEM of smelting ores DEMONSTRATED BEYOND QUESTION. COMPLETE PLANTS furnished to order of any CAPACITY, with ALL IMPROVEMENTS that experience has DEMONSTRATED as VALUABLE in this class of work.

Beyond question the cheapest and most effective machine of the kind now in use adapted to all grades and classes of ores.

This machine has been THOROUGHLY TESTED for the past TWO YEARS, under a GREAT VARIETY of CONDITIONS, giving most EXTRAORDINARY results FAR IN ADVANCE of anything EVER BEFORE REALIZED. A recent COMPETITIVE TEST at the Carlisle Mine in Mexico, showed an ADVANTAGE OF OVER 30 PER CENT in favor of THE DUNCAN. The amount SAVED OVER THE TRUE being sufficient to PAY THE ENTIRE COST of the machines EVERY MONTH OF THE YEAR. One of its MOST VALUABLE features is as an AMALGAMATOR. It saves all THE AMALGAM GOLD and SILVER that ESCAPES the BATTERIES, PANS or SETTLERS, making the machine worth MORE than ITS COST for THIS PURPOSE ALONE.

Baker's Mining Horse Power.

Possessing all the requirements of a first-class hoist and affording means for the continuous operation of a Pump or Blower, without interfering with a hoisting apparatus. It is made entirely of iron, no piece weighs over 300 pounds. At the ordinary speed of a horse, a 1,000-pound bucket of ore may be raised 120 feet per minute. The hoisting-drum is under the complete control of the man of the shaft, and is capable of carrying 500 feet of five-eighths steel rope. SEND FOR CIRCULAR.

NOTICE TO MINING MEN! SILVER PLATED AMALGAMATING PLATES FOR SAVING GOLD!

Get our Prices before ordering elsewhere. Samples furnished on application.

SAN FRANCISCO NOVELTY AND PLATING COMPANY, Removed to 108 First St.

JUSTINIAN CAIRE, Dealer in Mining Material, Agent, 521 & 523 Market St., San Francisco.

NOTICE TO MILL MEN.—All our plates are guaranteed to have the Full Weight of Silver agreed upon, and are all tested before leaving our Works, thereby avoiding the complaints about light-weight, made so often formerly before our starting in this branch of business. PLATES CAN BE FURNISHED AT ANY PRICE REQUIRED.

CALIFORNIA

ARTIFICIAL STONE PAVING CO.

(SCHILLINGER'S PATENT.)

—FOR—

SIDEWALKS, GARDEN WALKS, CORRIDORS, OFFICES, CARRIAGE DRIVES, STABLES and CELLAR FLOORS, KITCHENS, Etc.

The Courts here and in the East have decided that Artificial Stone Pavements with plastic concrete and in detached blocks, are infringements on the Schillinger Patent; and also, that when the plastic material is blocked off with a trowel and cut through far enough to control the cracking caused by shrinkage, that such pavement is in law the same as if laid in detached blocks, and is an infringement of the patent. All property-owners having such pavements laid without the license of the above Company, will be prosecuted.

ADAMANTINE Shoes, Dies and Crusher Plates

We manufacture the above Adamantine Shoes, Dies and Crusher Plates. They are in use on the hardest quartz in the United States and South and Central America, and have been for the last ten years; we warrant them to out-wear three (3) sets made of any other metal, and many report that they last from 4 to 8 times longer than any other make. They never break AT THE SHANK, and the wear is so light that little or no foreign matter gets mixed with the crushed ore.

Also CHROME CAST STEEL for Mining and General Use, of the finest quality.
For further particulars, address

American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Mining Share Market.

There is nothing specially interesting to report concerning the stock market, the Comstock not having developed anything new. The bottom of the Combination shaft is now well into the east side of the ore channel, which dips east about 45 degrees, and is passing into quartz, which is found to be more and more strongly mineralized as depth is attained. Contrary to expectation, no increase of water is perceptible, and as none is met with in the drift south, coming to connect with it from the 3200 level of the Hale and Norcross deep winze, it may be that these mining explorations have reached below the main water belt. As soon as a sufficient depth has been attained for a pump or well to the shaft, below the 3200 level, a station will be opened for a drift north on that level, to connect with that from the deep winze aforesaid. Nothing new is developed as yet by the diamond drill explorations eastward from the Potosi 300 level. Good work is being done on the 2900 level of Norcross, 600 level of Savage and above the 600 level of Curry, with excellent ore indications in each, and with present pumping progress the bottom level of the Osbiston shaft will be found before the end of the present month. The usual large amount of low grade ore continues to come from the old workings of the bonanza sections of the north and south ends of the lode, keeping the mills steadily running and a large number of men employed.

Bullion Shipments.

We quote shipments since our last, and shall be pleased to receive further reports:

Standard Con., June 2, \$7123; Mt. Diablo, May 26, \$10,168; Daly, 5, \$6019; Germania, 29, \$2410; Alice, 2, \$15,537; Silver Reef (for May), \$30,000; Hanauer, June 2, \$9440; Pascoe, 2, \$1530; Queen of the Hills, 2, \$1150; Alice, 5, \$13,750; Hanauer, 5, \$5600; Stormont, 5, \$2330; Crescent, 5, \$3600; Hanauer, 6, \$5580; Queen of the Hills, 6, \$3200; Germania, 6, \$4475. The shipments of ore and bullion out of Salt Lake City for the week ending June 6, inclusive, were 36 cars of bullion, 879,204 pounds; 17 cars of ore, 509,877 pounds; 10 cars of copper ore, 305,700 pounds; a total of 63 cars, 1,693,781 pounds.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, or beyond the time he intends to pay for it, let him not fail to write us direct to stop it. A postal card (costing one cent only) will suffice. We will not knowingly send the paper to anyone who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or some irresponsible party requested to stop it, we shall positively demand payment for the time it is sent. LOOK CAREFULLY AT THE LABEL ON YOUR PAPER.

UNCLE Sam has found it at last! A sure remedy for Torpid Liver, Sick Headache, Habitual Constipation, Chills and Fever, and all affections of the Kidneys and Liver. This is a New Compound, and one trial will convince you that it is the Cheapest and Best Remedy in the Market for Diseases of Kidneys, Liver and Stomach. If you want a pure vegetable compound, that is positively guaranteed to contain no mercury, go to your Druggist, and get a Bottle of the Arkansas Liver and Kidney Remedy. Price, \$1.00 per Bottle.

Dewey & Co.'s Scientific Press Patent Agency.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most reliable advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free.

HOOD'S FOUNDRY COKE.

Consumers are respectfully informed that owing to inferior brands of Coke having been sold in this and other countries under the name of "Patent Coke," the Glamorgan Coal Co. (Limited), Cardiff, in May, 1884, abandoned the title of "Patent Foundry Coke," substituting that of "Hood's Foundry Coke."

This Coke is exclusively used by the Selby Smelting and Lead Co., Union Iron Works, Professor Thomas Price, and other consumers here. Large quantities are regularly forwarded to Copper Smelters in Arizona and New Mexico, and also to consumers in Nevada and Salt Lake. The undersigned are the **SOLE IMPORTERS** of the above Coke, which is for sale in quantities to suit purchasers.

SEND FOR LATE CIRCULARS

SEND FOR LATE CIRCULARS.

**JENKINS PATENT VALVES.****Gate, Globe, Angle, Check and Safety.**Manufactured of BEST STEAM METAL. We claim the following advantages over all
other Valves and Gauge Cocks now in use:

1. A perfectly tight Valve under any and all pressures of steam, oils or gases.
2. Sand or grit of any kind will not injure the seat.
3. You do not have to take them off to repair them.
4. They can be repaired by any mechanic in a few minutes.
5. The elasticity of the Disc allows it to adapt itself to an imperfect surface.

In Valves having ground or metal seats, should sand or grit get upon the seat it is impos-
sible to make them tight except by regrinding, which is expensive if done by hand, and if done
by machine soon wears out the valve, and in most cases they have to be disconnected from
the pipes, often costing more than a new valve. The JENKINS Disc used in these Valves is
manufactured under our 1880 Patent, and will stand 200 lbs. steam. Sample orders solicited.
To avoid imposition, see that Valves are stamped "Jenkins Bros." For sale by

Impure Amalgam.

Ores containing such compounds of silver as cannot be treated satisfactorily in pans, or concentrated tailings of the pan amalgamation which contain chiefly such silver ores as has resisted the action of chemicals, will give the best result after having been subjected to a chloridizing roasting. The presence of base metals would, of course, render the amalgam impure. A certain amount of copper in the bar is of no great moment. If there is a great deal of lead the metal must be refined. In amalgamation in pans, if the ore renders an impure amalgam, the impurity can be best ascertained after the first discharge by taking a sample of about 10 grains of amalgam which is heated to a red heat by fire under draft, to get rid of quicksilver. The sample thus retested must be examined under the blowpipe. The late Mr. Knstel has described the method in detail. Black amalgam is first tried with the magnet on a small particle. If attracted there is a great deal of iron in the amalgam. There may be a little if it does not follow the magnet, and it then must be examined in a way described by Mr. Knstel. A small piece is introduced into a closed tube and heated to redness by an alcohol lamp. It generally gives out a whitish sublimate consisting of minute globules of mercury which can be detected by the magnifying glass or by a piece of flattened gold, which, when introduced into the tubes and rolled over in the sublimate, gets a coating of quicksilver.

Heated in an open tube, it sometimes colors litmus paper red. This proves the presence of sulphurets in the amalgam. Under such circumstances, a black sublimate appears, consisting of sulphur and antimony.

A small particle of bullion, metal, or retorted amalgam, is laid in charcoal and heated with the oxidation flame. A slight yellow coating indicates lead; a bluish-white, antimony; or the coating is yellowish, and, further off, a bluish-white, proving the presence of both lead and antimony.

If there are no other metals in it but iron, there is no remedy save better roasting. The chlorides of other base metals can be destroyed by using quicklime, pulverized lime rock, or clean wood ashes. One or one and a half per cent of lime is charged with the ore. After a quarter of an hour's time, a small portion of the ore is taken from the pan, put into a porcelain cup, and, by means of a piece of copper, stirred with more water and a few drops of quicksilver. If the quicksilver is covered with a black coating instantly, some more lime must be added. Fifteen minutes later another sample is taken in the same way, and so on until the quicksilver does not appear black, or only slightly so. Too much lime is injurious to the character of silver. This method is only a temporary remedy. It can be better executed in the furnace.

A BREAK in the spur-wheel connected with the hoisting machinery made it necessary to shut down the Crown Point and Belcher mines pending repairs. The shutdown throws 200 men out of employment, besides the force engaged at the Vivian, Santiago and Mexican stamp mills on the Carson river. The break resulted from the machinery getting out of line by the settling of the ground in the vicinity of the shaft. It will require three weeks to get the hoisting machinery in running order.

Mill for Crushing Bullion for Refining.

In refining coppery bullion on the Comstock, the bullion in lumps from the retorts is thrown into a hot roasting furnace, after a regular day's work, and left until next morning. This is done for two reasons: primarily, to facilitate crushing, and, subordinately, to drive off any contained quicksilver. All bullion is crushed in a Chili mill, the castings of which were made from a rough sketch (similar to that shown in the engraving) given to the foundry. A. D. Hodges, Jr., describes this mill before the American Institute of Mining Engineers, as follows:

The pin is stationary, the wheels rolling around on it. The mill was run in a small room, the floor of which was covered with

gain of 97½ pounds (0.07 per cent), which probably represents the wear of the wheels and pan.

Foundry Notes.

The Risdon Iron Works are building the large engines and boilers for the new cable railroad in Oakland. The boilers used will be of the Hsine pattern. The engine-house is located at Twenty-first street and San Pablo avenue.

The Pacific Rolling Mill is putting in the turn-table for the Oakland cable road, at the corner of Seventh and Broadway. It will be slightly raised above the surface of the street, after the fashion of the turn-table at the foot of Market street, in this city, so as to afford a slight incline for starting the cars. The turn-

IRON CHILI MILL FOR CRUSHING BULLION.

sheet iron plates to prevent loss and insure cleanliness. It worked well and needed no repairs or special attention. One Chinaman did the crushing, sifting the pulverized material through a No. 20 wire screen. As the mill was run very irregularly at the Lyon mill, it is difficult to state its exact crushing capacity. According to the accounts the mill crushed about 100 pounds of sulphurized white and 200 pounds of calcined base bullion (including sifting) per hour. The cost of crushing, reduced to terms of retort material, was 0.175 cents per pound for white bullion and 0.088 cents per pound for base. The average would be (at one part white to four parts base) 0.105 cents per pound of retested bullion.

The base bullion crushed almost completely, the average percentage of the lumps left during two years being 0.55 per cent. The amount of lumps from crushing the sulphurized white bullion varied considerably according to the manner of firing the sulphurizing kettle, and also according to the percentage of melted bars (from the crude bullion assays, etc.) put in the kettle. The average for two years was 6.86 per cent.

The wear of the mill was very small. The returns from 138,634½ pounds charged to the mill were 138,732 pounds, showing an apparent

table is 24 feet in diameter with concrete foundation. The excavation is large enough to accommodate the tail-pulley.

The National Iron Works are building a new battery, called the Kendall Rocking Battery. The particular advantage claimed for this machine is that the roller wears down smooth and evenly in the cradle and thus has always a round face. The cradle, which is lined with iron plates, keyed in so that they are easily adjustable, vibrates in a ratchet frame, and the roller is guided by a simple contrivance. The machine when completed weighs 4500 pounds, and will do the work of a five-stamp mill. The roller weighs about 1100 pounds. A machine now at work at Altaville gives perfect satisfaction, and with ten miners' inches of water for power, crushes 12 tons of ore a day. The cost is only about \$400.

ERA, Idaho, is a new camp, the principal mine in which is the famous "Horn Silver" now owned and worked by the Bannock Mining Co. The company is now erecting a 20 stamp dry crushing mill, under the supervision of J. K. Owens. The town has nearly 100 buildings of all descriptions, and there are probably 500 inhabitants.

Dykes' Rock Crusher and Pulverizer.

Hugh J. Dykes, of Berkley, Alameda Co., has received, through the MINING AND SCIENTIFIC PRESS Patent Agency, a patent for a rock crusher of that class in which the rock is crushed and pulverized between a fixed and movable jaw.

In this device the fixed jaw is mounted on a vertical plane in one end of the frame, and is adapted to be removed therefrom and be set up or adjusted by the following construction: The ends of the jaw have tongues, which slide down within and are seated in grooves in the frame, said grooves being wider than the tongues. In angled seats in the rear of the frame are inserted wedges, which are cored out and form grooves in which the head of bolts are fitted. These bolts are provided with nuts on the outside, by which said bolts may be set up so as to hold the wedges against the back of the jaw or bed. By dropping or raising the wedges, the jaw may be adjusted closer to or drawn backward from the face of the movable jaw, and may be held in the position to which it is adjusted by setting up the bolts. By loosening said bolts the gibbs may be taken out and the jaw may be removed by raising it out of the grooves.

The movable jaw is pivoted on a shaft, which passes through the frame and is provided with pins by the removal of which the shaft may be taken out, so that the jaw may be thrown back out of the way, said jaw turning on its end point and resting when thrown back on a shaft in the frame behind. Pivoted on a cross shaft is a lever, the forward end of which is connected by a link with the rear of the jaw or head. The rear end of the lever is slotted and receives a strap which is pivoted to said lever. The strap is operated by an eccentric.

By means of the lever and link the inventor obtains a compound leverage, by which to vibrate the movable jaw. It is so arranged as to be operated by hand if desired.

The face of the movable jaw is provided with a shoe which has a dovetailed tenon, made transversely and horizontally upon its back and fitting within a correspondingly beveled groove in the front of the jaw or head. The shoe may thus be slipped out of the jaw for cleaning purposes or for reversing it, or for the substitution of another shoe.

Though fitted in by a dovetailed connection, the shoe is held firmly in place by the sides of the frame, and requires no other means to hold it on its seat. The corrugations on the faces of the two jaws are of peculiar arrangement. They are made only upon the ends of the faces, the centers being left smooth. The corrugated faces, therefore, serve for crushing the rock, while the smooth centers serve for the pulverizing. The corrugations on each side are uniform as to the space they cover, which provides for the reversal of either jaw. Another feature is that the corrugations on the face of one jaw are vertically arranged, while on the other they are arranged in horizontal levers. This gives a better grip and more effectively accomplishes the crushing.

A SCIENTIFIC expedition under the direction of Professor Scott leaves Princeton next Monday for the West, the main object of the expedition being to make a geological survey of the Uintah mountains in Western Utah and Wyoming.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

A Theory as to the Management of Mining Employes.

EDITORS PRESS:—I have long had the conviction that a prudent mining manager, who had been careful to select, say 20, highly-recommended miners, and was paying them extra wages, would do more and better mining work than could possibly be done by another manager who had to depend on 30 employes taken at random as they came along seeking employment.

Whether this theory is capable of being put into profitable practice is something I have not yet been able to prove except on a small scale, and one object I have in stating it here is to induce, if I can, some of the practical mining readers of the PRESS to give their opinions on the subject. That it is an important question cannot for a moment be doubted.

We are continually witnessing contests between employere and employes, as to wages, hours of labor and cognate matters; and as long as there is no bond of mutual respect, sympathy, interest, or friendliness between such parties there must be the strikes and losses which naturally follow them.

How to Put Theory Into Practice.

A mine-owner located in a district where miners' wages are \$3 per day may, as the first step in carrying out his plan, resolve to pay \$3.50, or even \$4, to the men he desires to employ. To secure the right kind of miners he may advertise, write to mining friends, or in person, or by agent, visit important mining centers. By careful inquiries, free conversation with applicants, and the aid of a sound knowledge of human nature as it is revealed in physiognomy, he will be able, after considerable toil and expense, to get his 20 employes together. He will have committed some mistakes and have been made the victim of perhaps one or two designing men, but he will be in a fair way to make a satisfactory start.

Every right-thinking man in such a crew will reason in this way: "I am to get extra wages without extra hours of labor; no attempt will be made to watch or drive me; as long as I attend zealously to my work I will be, as nearly as possible, my own master. Surely that is an improvement on the ordinary way of managing miners, and it ought to succeed. It will be to my interest, as well as to the interests of my 19 co-workers, that it should prove successful, and we ought to strive toward that end."

These views will be interchanged among the men, and there will be united, harmonious action to give them effect. Every miner will act with a determination to make the work, so far as he is concerned, go on satisfactorily. In the breaking down of ore, care will be taken to exclude waste, and at the close of each day the owner of the property, as the result of the skill and industrious zeal of his workmen, will have obtained, in thoroughly effective, creditable work, far more in value than the extra wages he had agreed to pay. He will, moreover, have a quiet, orderly class of people around him. There will be no intoxication, no profanity, no systematic gambling and no fighting or murderous plottings in such a camp. The families, too, of the right kind of miners will be on a higher moral plane than those of the mere here today-gone tomorrow tramp miners, with whom whiskey, pistols and cards seem to be the three primary desiderata of existence.

The thirst for knowledge displayed by the children of the high-class miners will spur the mine-owner on to provide reading-rooms, libraries and lectures, so that the next generation may compare favorably with the present. In a community under such auspices, churches, schools, colleges and education in its widest sense will have encouragement, and civilization will radiate from it as a center of progress and enlightenment. The man who thinks that a mine-owner who pays out daily a round sum of money as extra wages for extra mining ability in the way above indicated, is a simpleton who parts with it very easily and gets no adequate return, must have a strange idea of human nature, and know extremely little of the possibilities of doing or not doing effective mining work in the lower levels of a mine.

What Objectors Say in Relation to This Theory.

"Your plan will not work at all," says one person. "The men you employ will give you no more work than the ordinary \$3 men. Your being liberal will make them regard themselves as privileged favorites, who can do as they please, and extra work will be about the last thing they will give you for extra pay." Says another: "You will find plenty of mining superintendents willing to recommend miners as first-class workmen who are the commonest kind of hands. When you find you have been deceived and try to get rid of such men you will get yourself into trouble. They will assert their qualifications, and demand traveling expenses for being misled as to permanent employment."

Says a third: "The only true way to get a good crew of miners is to take every man that

comes along and prove what he can do. After a time you will have picked out as many good men as you want, and they will do just as much work as your high-priced miners. If they do not, a watchful foreman will weed them out and the rest will be scared into increased activity. You cannot get men in this country who will work from noble motives. They work for so much money and they will do just as little as they can to secure it."

I listen to these and similar mistaken opinions, but remain as thoroughly convinced as ever that my theory is capable of being put into profitable practice.

What has been Done in a Small Way.

I once paid a strong, skillful miner \$5 a day when \$4 was the current rate, to open a 60-foot tunnel in blasting limestone. When finished, the work, including materials, cost me just \$3.60 per foot. No miner would have taken it by contract at less than \$6 per foot.

I hired two able miners at \$4.50, when \$4 was the common rate, to do surface work. It was cold weather, and I was not particular as to hours if they gave me a fair day's work. These men could not have worked harder under contract, and I never got so much labor for a given sum of money as they gave me.

But a neighbor complained that my mode of treating my men made him trouble with his miners. A few days thereafter I went to my neighbor's tunnel and found one man on guard and five enjoying a comfortable sleep. They explained that they were kept at the mine from before daylight in the morning until it was quite dark at night, and they would not under such treatment do vigorous work.

Summing Up the Case.

I know there are some men who will invariably take advantage of an employer's liberality, but they are the exception and not the rule. There would be no room for that class in the carrying out of the theory I have set forth. The men to be employed must be capable of appreciating generous treatment. If they failed to display that capacity they would be got rid of at the earliest possible moment.

A mine managed on the plan indicated would have no need of a "driving" foreman. Every workman would know his work and do it without nagging or interference. A mine run on that principle would be easily managed. Its works would always be in good order, and caves and accidents would be reduced to a minimum. I may be wrong, of course, in holding such views, but all the same I should like to see them put into practice. CENDA.

Mounting the Lick Telescope.

The Lick Trustees have awarded the contract for mounting the 36-inch objective (now in the hands of the Messrs. Clarke of Cambridgeport) to the firm of Warner & Swasey, Cleveland, Ohio, for the sum of \$42,000. Messrs. Warner & Swasey were successful in a competition which included most of the celebrated makers of the world. One firm of celebrated makers (the Repsolds of Hamburg) declined to compete on account of the short time available for the purpose. The mounting proposed by Messrs. Warner & Swasey will include every one of the improvements which have been lately introduced into the mountings of large telescopes, with the addition of one or two improvements peculiar to themselves.

The telescope is to be 57 feet long; the diameter of the tube is 42 inches. The tube is suspended at the middle, and the point of suspension is to be 37 feet above the floor of the dome. The axes on which the tube moves are supported by a heavy iron column, 17x10 feet at its base.

Provisions are made by which it is possible for an observer at the eye end of the telescope to command all the possible motions, and these same motions can also be controlled by an observer stationed on a small balcony 20 feet above the floor. It is expected that, in spite of the great size of the telescope itself and of its great weight, the mechanism will be so delicately adjusted as to render the use of power unnecessary.

Messrs. Warner & Swasey are to have this mounting completed in April, 1887, and sometime during the summer of 1887 the glass will be brought to Mt. Hamilton, where the mounting will already have been erected under the great dome, now building at the Union Iron Works of this city, so that one may look forward to the completion of the Lick observatory sometime during the next year. It is impossible without an accurate description to give any complete notion of the excellence of the provisions which have been made by the Lick Trustees. A rough idea may be had by considering the cost of the various parts of the great telescope, dome, mounting, etc.: Cost of the dome, \$56,850; cost of the mounting, \$42,000; cost of the visual objective, \$53,000; additional cost of the photographic objective, \$13,000. Total, \$164,850. Beside these sums, several thousand dollars will be required to put the instrument into its final completed state.

At this season one often finds that a can of fruit has soured so as to taste badly, even after a thorough scalding. In such a case a little soda will sweeten perfectly. Skim carefully as it boils up.

Attorney-General Garland on Debris.

The following is an Associated Press dispatch dated Washington, June 10th: Attorney-General Garland, to-day, submitted to the Senate Committee on Commerce an opinion in regard to the intervention of the General Government for the protection of the navigation of the Sacramento and San Joaquin rivers from impairment by the continued discharge of hydraulic mining debris. He says: "The Constitution gives Congress power to regulate commerce, and as a subsidiary right, this regulating power is not confined to the subject of traffic, but extends to the channels through which traffic is carried on, and therefore embraces jurisdiction in Congress over the navigable waters of the country as to all things appertaining to them as highways of trade and intercourse, and especially as to whatever affects their navigation. Congress controls the building of bridges over navigable streams, establishes lighthouses, prescribes regulations to govern vessels and adopts measures for the improvement of navigation, even to the extent of changing the rivers. For such and like purposes these waters are the public property of the nation and subject to all requisite legislation by Congress. This power to regulate was conferred on Congress only, the States having abdicated all control over commerce, and a high and imperative duty was laid on the National Government to protect and encourage commerce. The effect of this as to navigable waters is to establish them as highways, open to the free and unrestricted use of all persons engaged in foreign or interstate commerce." The Attorney-General continues at length his argument to show the undoubted right of Congress to legislate in all matters appertaining to the interests of commerce. He says the papers submitted to him furnish convincing evidence that the navigation of the Sacramento and San Joaquin rivers and their tributaries has been seriously impaired and in some places destroyed, and is threatened with complete destruction by washings from the mines worked by the hydraulic process, the evil extending to the Suisun and San Pablo bays, and even to the great bay of San Francisco. The navy yard at Mare Island and other Government works must be seriously damaged if hydraulic mining, as now conducted, is allowed to continue. Although the rivers named lie wholly within the State of California, they communicate directly with and are navigable from the sea, and consequently, are highways of interstate and foreign commerce, and fall clearly within the jurisdiction of Congress. It cannot be doubted that the filling of the channels of these great highways of commerce is a public nuisance, stupendous in extent and injury, which loudly calls for the interference of a restraining power; but that that restraining power be exerted by the Government of the United States without additional legislation, there being no provision in the criminal legislation of Congress making it an offense to obstruct navigation. There is no remedy under the present law by indictment, as a thing cannot be an offense against the United States except it has been declared such by an act of Congress.

Another means of remedy is through the United States Courts by an information filed and a suit brought by the Attorney-General. The Supreme Court has recognized the fact that a court of equity may take jurisdiction in cases of public nuisances by that process. The subject of the proper form of remedy against nuisances affecting the United States came before Attorney-General Cushing in the matter of Wankegan breakwater, and the conclusion reached by him was that it was the undeniable law of the land that the Attorney-General has authority, when the occasion requires the abatement of a public nuisance to navigable waters, to file an information therefor, and a bill of injunction in the proper court of the United States.

The Attorney-General concludes: "I am not called upon to consider the effect of any action of the State of California authorizing the injurious use of the above-named rivers as receptacles of debris produced by hydraulic mining, supposing such action could have any possible validity in view of the express conditions on which the State was admitted into the Union, viz.: 'that all navigable waters within said State shall be common highways and forever free, as well to the inhabitants of said State as to the citizen of the United States, without any tax, duty or impost therefor.' No one pretends that the State has in express terms given any authority for the injurious use of those rivers, and the argument that such authority may be collected by implication from the legislation of the State, or the United States, or both together, has been completely met and overthrown by the learned Circuit Judge of the Ninth Circuit, in his opinion, in the important case of Woodruff vs. the North Bloomfield Gravel Mining Company, in which the facts, now before me, were held to constitute a public nuisance that might be properly enjoined on a bill filed by a private person specially aggrieved.

"Looking, then, at the question submitted, in the light of reason and authority, I cannot entertain a doubt that the evil complained of is leveled at a great national right, which is placed by the Constitution under the peculiar protection of the United States; that it is a case specially calling for the interposition of the restraining arm of equity, there being an entire

absence of the ordinary remedy at law by inheritance, and that it is the duty of the United States to take prompt action, either by an information in chancery or by legislation, making it penal to obstruct or impair the navigation of any waters under the jurisdiction of the United States. And in view of the urgency and importance of the subject, I take leave to recommend that it be brought to the attention of Congress at the present session."

A communication from Secretary Endicott calls attention to the suggestion of the Attorney-General, that prompt action be taken either by information in chancery or by legislation. The Secretary agrees with the Attorney-General that legislation is demanded, and recommends that these obstructions be made indictable offenses, with suitable penalties, and also that some provision be made for bringing hills in equity in the name of the United States, with stringent provisions for the enforcement of the courts' decrees.

Comstock Bullion.

The Virginia Chronicle says: An abstract statement of the bullion product of the mines in Storey county for the quarter ended March 31, 1886, has been filed at the Recorder's office by Assessor George Henning.

During that period 68,288½ tons of ore were extracted and crushed, the bullion product from which foots up \$816,464.96.

The total cost of mining, transportation and converting it into bullion is given at \$834,879.64. The product was divided as follows:

	Tons.	Val. per ton.	Total.
Con. Cal. & Va.....	30,093	\$11.60	\$349,370.80
Belcher.....	10,409	11.84	113,103.79
Crown Point.....	11,263	12.62	142,274.83
Yellow Jacket.....	11,789	12.66	149,303.09
Overman.....	1,740½	10.81	17,955.29
Kentuck.....	2,989½	13.20	39,457.66
Total.....	68,288½		\$816,464.96

Increase in the Bullion Yield.

The above shows an increase of 8000 tons over the output during the previous quarter ending December 31, 1885, and an increase in the bullion product over that period of nearly \$100,000. It is estimated that the bullion product for the current quarter will foot up \$1,000,000.

According to the above statement the cost of production of bullion from ore extracted from the Con. Cal. & Va. mine during the last quarter leaves a margin of only \$912 to be divided among shareholders.

In the Crown Point the figures show a balance of \$6000 in favor of shareholders, while in the Belcher and Yellow Jacket the cost of production over the gross yield is stated at \$6000 in the former and \$22,000 in the latter.

The deficit in the Yellow Jacket was made good by the declaration of a left-handed dividend during the last quarter.

The bullion yield from Kentuck and Overman ore also falls below the cost of production, showing a balance of \$7000 against the shareholders in the former and nearly \$1000 in the latter.

Turning back to the year 1876, the Assessor's books show that the yield from the Con. Cal. & Va. mine during the first quarter exceeded \$6,000,000, on which Storey county received \$227,000 in taxes.

The tax on the yield for the first quarter of the present year is less than \$2000.

The Manufacturers' Association.

The last meeting of directors of the Manufacturers' Association was fully attended and the occasion of an extended and interesting review of the purposes and progress of the association, of the results which have been and may be accomplished through its efforts, and a warm discussion upon the policy to be adopted to make its work vigorous and effective in the future.

The subject of more earnest effort to secure to our manufacturers and producers equal advantages upon Government work and supplies was renewed, and the secretary instructed to communicate with our Senators and Representatives in Congress, requesting their active cooperation in obtaining for the use and benefit of our producing and manufacturing interests early and explicit information of all work and articles required in the various branches of Government service, so that our people may be enabled to compete favorably as to time and conditions with Eastern manufacturers. Also that in issuing specifications for articles needed, instead of requiring those of special and exclusive name and manufacture, others of equal quality and price may be substituted and accepted.

It being desirable, in view of the common benefit to be derived, that there should be united interest and action on the part of all producing and manufacturing interests in this State, so that the largest and most concentrated influence may be exerted for the advancement of local industries, it is requested and earnestly urged upon all persons engaged in any productive or manufacturing enterprise, of whatever character or wherever located, in this State, to communicate with the secretary of the Manufacturers' Association of California, giving their name and address, description of articles made or produced, amount or gross value of annual output, and average number of persons employed, together with any suggestions they may volunteer relating to the general advantage.

Improved Beet Sugar Machinery.

The United States Department of Agriculture continues its fostering work for the home production of sugar. The latest contribution to this end is a special report just prepared by Prof. H. W. Wiley, chemist of the Department, who was sent to Europe last summer to inspect the latest improved machinery and processes in this great European beet sugar industry. The results of his investigations are given in an elaborate illustrated report which we have no doubt can be obtained by those interested in sugar production on application to the Commissioner of Agriculture, or to any of California's senators or representatives at Washington. We have thought that we could best call the attention of our readers to this report by reproducing from a large plate a reduced view of a very ingenious arrangement for elevating, cutting and conveying the chipped beets to the cells of the diffusion battery.

This report shows that the best establishment, the sugar factory at Abbeville, in France, is arranged so that the central factory receives the juice from several "raperies," or stations where the juice is extracted from the beets, and the juice is carried by pipe lines laid underground from these raperies to the central factory, where the juice is freed from its impurities and condensed in the vacuum boiler into sugar. This method, of course, obviates hauling the beets long distances, as each station works up those grown in its district, and shoots the juices through the pipes, by a force pump, to the central factory. The plan seems to be much like the central cheese factory or creamery, which works up the milk or cream brought from all the farms within a radius of several miles.

The engraving gives a view of the interior of one of the raperies, and it is certainly arranged to do the work with a minimum of labor. The beets are shown entering this factory at the left and rear of the apartment, thence passing up the inclined elevator until they are dropped into the carrier, which in turn drops them into the open mouth of the cutter, which is seen aloft with the operator beside it. This cutter is directly over the center of the circle, around the circumference of which are seen the diffusion cells and to each one of which the spout or the chute from the cutter swings. In all the improved European factories the cutters are placed above the cells. It is more convenient to elevate the beets by suitable apparatus; it would be to carry the chips to the proper altitude. In all circular batteries the cutter is placed immediately over the center of the battery. The chips fall into the upper expansion of a pivoted chute which is placed at an angle of about 40 degrees. With this inclination the chips fall readily down the chute and into the opening of the cell.

The bottom of the chute is furnished with a hinged nozzle which, on being raised, arrests the discharge of the chips until the chute is pushed to the next cell, a procedure which takes only a moment of time. Thus the filling of each cell is entirely automatic, and the arrangement is the most simple as well as the most effective possible. Usually the cutter has a capacity greater than the battery, so that often its operation is stopped while the feed channel is changed from one cell to the next. It can be done, however, very well with the cutter in motion.

In the second place, the circular disposition allows the exhausted chips to fall into a common pit, whence they are easily removed by

an elevator to the presses. This pit, circular in form, is furnished with a bottom sloping toward the center, over which the chips readily move when discharged from the cells. Very little manual labor is therefore required to convey them to the elevator.

Lastly, the circular disposition permits the apparatus to be put up in a much more compact form, and thus diminishes the cost of the building and other necessary fixtures. There are many minor points of advantage, and in the erection of new plants at the present time this disposition of the cells in a circle is almost always preferred. The general view of the circular disposition, showing the method of charging and giving a notion of the arrangement of the

A LARGE ORE BODY.—The ore body encountered some four weeks ago in levels Nos. 1 and 2 of the Engine shaft, in the Paradise valley, continues to increase in size and richness. The Engine shaft is in No. 4 tunnel, about 200 feet from the surface, and levels 1 and 2 in that shaft are respectively 50 and 100 feet below the tunnel. In No. 2 level the ore body was opened on Thursday last 115 feet along its course, and the lead averages nine feet in width and the ore between \$150 and \$200 per ton. As no one has yet been enabled to see into the solid earth, though "diviners" or "dousers" claim to have the gift, it is impossible to tell the extent of the ore body, but the value of the ore in sight is estimated at over \$500,000. This

Lake Valley Concentrates.

The Sierra Grands mill fired up on the 20th of last month, and was working satisfactorily when our representative was there a short time since. Among the notable improvements inaugurated by Walter C. Hadley, who is now in charge of the company's mill and mines, we were struck by his plan for securing an economical supply of water. This was effected at an expense of less than \$125, by making use of the water supply in the 400-foot shaft west of the plant, higher up the bill. The column

of water rises 200 feet in this shaft, and Mr. Hadley placed two steam pumps in it, and the plant is now furnished with its entire water supply from this source, thus reducing the running expenses about \$500 per month, providing that the water supply in the shaft is permanent, which is very generally conceded. Formerly the water supply was forced to the mill from a distance of four miles by means of a pumping outfit stationed there.

Up to the first of last month, the management had failed to economically chloridize the flue dust; but now, owing to the auxiliary fires, enlarged dust chambers, the reduction of the draft by means of dampers and a novel contrivance to facilitate the roasters, carrying more load and retaining it longer, the flue dust, which is always a source of loss to reduction works, is satisfactorily treated and disposed of. The plant is in fair condition, and when our representative was there it was running smoothly and more economically than at any previous period in the history of the enterprise. Eighty men in all were on the pay-roll.

A 100-foot contract is now being completed in a new shaft not far from the Bridal Chamber to open up new ore bodies. Two hundred and fifty men will be required to keep the mill supplied with ore; but owing to the prospect that the management will soon enlarge the plant, and otherwise improve it, which will necessarily cause a suspension of operations for a while, we would not advise miners to go to Lake Valley with the idea of securing work.—*Socorro Bulletin.*

THE FORTUNES OF MINING.—An item is going the rounds stating that a telegram ordering the permanent shutting down of the Granite Mountain mine, in Montana, was delayed through the carelessness of a telegraph employee and did not reach the superintendent until two days after the date upon which it was transmitted over the wires. During that interval an important ore development was made and the mine is now paying handsome dividends.

Work would inevitably have been abandoned had it not been for the neglect of the careless attache of the telegraph office. The management of the mine have recently made the attache a handsome present of \$5000 in coin. This is probably the first instance on record of an employee receiving a liberal reward for neglecting his duty. The Granite Mountain mine is located near Phillipsburg, the county seat of Deer Lodge.

PASTEUR'S GREAT DISCOVERY.—The *Tribune's* London cable special says: The English Scientific Commission appointed to inquire into Pasteur's process has completed an elaborate investigation and is preparing a report which will affirm the efficacy of his method as a cure for hydrophobia and will rank it among the chief scientific discoveries of the century.

THERE are over 200 artesian wells in Kern and Tulare counties, all with a good flow of water.

INTERIOR OF FRENCH SUGAR STATION FOR CUTTING AND EXTRACTING JUICE FROM BEETS.

necessary apparatus, is given in the engraving.

We hope to see ere long beet sugar factories on this coast as well equipped as those of France. The report of Prof. Wiley shows how fine is their machinery and how successful its operation. With a country so well fitted for beet growing and sugar making as California it would seem but the part of wisdom for our capitalists, who have so much idle money, to put part of it in such enterprises to secure a good interest for their money, and at the same time distribute good returns among the beet growers and furnish cheap sugar for our fruit canners. The Alvarado factory has done well with limited capital and facilities. It should induce our rich men to go into the production on a grander scale, and thus minister to our general prosperity and progress.

The famous Black Bear mine, in Siskiyou county, worked by Lieutenant-Governor Daggett, is again paying. The *Yreka Union* says the prospects of a fortune are good.

ore has been developed at the greatest depth ever reached in this county, where, notwithstanding mining has been carried on for years, there is not a shaft, with this exception, over 300 feet deep. The Paradise bids fair to be the best mine in the State, and at the present time it is certainly the richest.—*Winnemucca State.*

MICA.—In Groton, New Hampshire, they are working a mica mine profitably. The ledge is really a large hill of solid rock, composed in the regular order after the covering of schist is removed—quartz, mica, feldspar, again and again, down through the hill to an uncertain depth. The work of blasting has been carried forward there until an open drift has been cut 300 feet long, at least 40 feet wide and not much less than 50 feet deep. Branching off from this cut is a tunnel now about 20 feet long and 20 high, drilled horizontally into the ledge. Small iron tramways lead to the dump, and little cars, pushed by hand, carry the refuse rock out of the way.

Passing Events.

Some new mines have been discovered in the extreme southern part of this State, about 40 miles south of the Needles, but so far little is known of them.

The opinion of Attorney-General Garland on hydraulic mining, which we give on another page, is looked upon with great disfavor by those mining gravel in California.

A new gold "excitement" has broken out at the Kimberly fields, in Western Australia, in a region which local papers predict will be the largest gold field in Australia. With new gold fields in Australia, Patagonia and South Africa, those who like to visit distant regions will have several choices of location.

Two streams in the mountains are now all running full from the melting of the snows, and the mills which are run by water power now have an abundance.

PROSPECTORS from Metal Landing, 40 miles south of the Needles, on the Colorado river, report rich discoveries of gold. Men are leaving the Needles for the new camp.

Gold in Sulphurets.

The usual association of gold in quartz veins with sulphurets is well known. In gold regions the sulphide of iron (iron pyrites) is generally gold-bearing, as is also the arsenide of iron (arsenical pyrites or mispickel). The gold in these sulphides and arsenides is probably diffused mechanically and not in chemical combination, as some have claimed. Prof. Wm. P. Blake states that the experience of many years in the examination of gold veins and gold ores sustains the conclusion that the gold is mechanically diffused. Although the metal is generally invisible in the undecomposed and brilliant crystals of pyrites, it becomes apparent when such crystals are decomposed by oxidation air or by artificial means. Decomposition by nitric acid is frequently resorted to as a test of pyrites for gold. As a result of such decomposition we frequently find particles of gold, ragged in form, but of comparatively large size. So, also, when pyrite is changed to limonite by oxidation, and without losing its form, gold which probably was before the change scarcely visible, becomes distinctly visible in contrast with the brownish red color of the iron oxide. Deflagration of pyrites with nitrates of soda (Holland's process), which is simply another method of oxidation of pyrites, also liberates gold from arseniferous pyrites, and permits it to be seen when the oxide of iron is washed away. Roasting produces the same result.

In amalgamating gold ores it is common to find that fragments of either raw or roasted pyrites, but more especially the roasted, adhere to the quicksilver by a single point only, where the gold comes to the surface and finds contact with the quicksilver. Crushing and providing the pyrites also liberates the gold, but has the disadvantage of breaking up the ragged gold at the same time, and the color of the pyrites is often so nearly like the gold that it is difficult to distinguish one from the other. The State Mineralogist of California in his report of 1884 describes large crystals of pyrites from an El Dorado county mine, on the surface of which large globular masses of gold appear.

The opinion that gold is mechanically and not chemically disseminated in pyrites is defended by Adolph Ott, Henry Wentz and others. Ott, in the journal of the Franklin Institute, gives several good reasons in support of his opinion, and cites Bergmann, who, as early as 1735, showed by digestion in nitric acid, gold to exist in pyrites in small annular grains, thus proving the metal to exist in the state of rough limonite, and not of composition in the pyrites. Joseph Black, in his lectures on chemistry, appears to have held the same opinion.

It is the opinion of Prof. Blake that the gold in pyrites is generally in a crystalline condition, not compactly aggregated, but spread in a network in parallelism with the crystalline planes of the pyrites, forming a rude crystalline skeleton or crystalline fragments. The late Prof. John Torrey, of the U. S. Assay Office, showed that after treatment of pyrites with nitric acid gold appears under the microscope in laminae in filiform and spongy particles. An interesting example of spongy gold, occurring in a mine at Angel's Camp, in this State, was brought to the notice of Prof. Blake by the late Dr. Hill. It has the appearance of precipitated gold and the form apparently of a crystal of iron pyrites, looking as if it had been aggregated in a cavity left by decomposing pyrite. It is very light and is easily impressed and burnished by the nail. It is a good example of spongy, crystalline gold of natural origin.

A BIG OIL WELL.—They have put a cap on the new oil well at the Paente ranch, Los Angeles county, and are now talking of building a pipe line to the city of Los Angeles. The well is 20 miles east of that place. It has only been recently bored and was producing 50 barrels a day until one day last week, when the borers, in sinking the well to a lower depth, struck a new stream of immense strength, which threw the apparatus out of the hole with great violence, hurling a man 60 feet in the air, who barely escaped with his life, catching on the top of the derrick, thereby saving a heavy fall. The well threw out 500 or 600 barrels of oil in a few minutes, and flowed all over the place. The flow subsided soon, but may be renewed. It is hoped the well will now produce steadily some 150 barrels a day.

New Gold Fields.

The Kimberly fields, in Western Australia, are beginning to send nuggets in to Sydney. Some of these run from half an ounce up to 190 ounces. The gold is only slightly water-worn, so it cannot have traveled far from the quartz where it originated. A rush has already set in from Western Australia and from New South Wales. Large numbers of diggers, storekeepers and others have found passage round westward, while others from Victoria, New Zealand, etc., have arrived in Sydney, whence steamers are being specially laid on, most of which will call at the Queensland ports en route to pick up additional miners. The two places of debarkation are Port Derby (King's sound) and Cambridge gulf.

It is stated by some parties that this will be the largest gold field in Australia. The laboring whites men ask 15 shillings a day for work, and black or Chinese labor is scarce. It has been estimated by Mr. Hardman, the Government Geologist of Western Australia, that an auriferous area of country, extending over some 3500 or 4000 miles, exists. The latest information is a telegram from Perth, which states that a miner named Morgan has returned to Port Derby with a large quantity of gold, including a nugget weighing two and a half pounds of solid gold.

The newly-discovered Patagonia gold field extends from Cape Virgin, on the northern shore of the Strait of Magellan, along the Atlantic shore some 50 miles. The gold country is easily accessible, and the deposits are known to be rich.

There is a gold field also in the Transvaal, South Africa. In the closing week of last year 2560 ounces of gold were received at Natal. Farther north, rich deposits of gold and baser metals have been found south of the Zambezi. This region is but little known to white men, but if it is as rich as represented, tens of thousands of white miners will soon be in Central Africa. Northern Thibet is another region which is known to contain vast quantities of gold, which will very soon be extensively worked. It is an upland region, with underlying rock, and there is from 16 to 20 feet of soil, all of which is auriferous. Then there is gold in abundance in Manthuria. This is a region in China, near the Russian possessions. From Madagascar reports come of wonderful gold finds.

As all these places are at great distances from us, it is difficult to get any very definite information concerning them. The further gold fields are away, the richer they appear to be to those who read of them. To none of these places mentioned has a poor man any business to go, with only money enough to pay passage to the fields. The stranger is at great disadvantage in every way. It is bad enough to land "broke" in a camp in our own country, but the regions referred to would be had places to strike with empty pockets. Moreover, so little is so far known of these that only the most adventurous would start without plenty of money.

MINING CLAIM DEVELOPERS.—Says an exchange: It takes three classes of men to develop a mining camp. First, the prospector who finds the ledge, but rarely does anything more than assessment work, and usually avoids that if he can; next the small mining capitalist, who "bonds" the mine or takes a share of it for development work, and expends two or three thousand dollars on a chance of making several hundred thousand dollars; lastly, the San Francisco, or Denver, or Chicago, or New York, or London operator, who will pay a million dollars for a property which can be made to pay dividends on that sum, but who will not even send his experts to look at an undeveloped property.

MINERAL LAKES.—A member of the Geological Survey says that Salt Lake will be of great value in the near future, not only on account of the common salt it will produce, but also for the sodium sulphate it contains. The latter is separated in a flocculent precipitate by the cold weather of midwinter and annually thrown on the shore in enormous quantities. There are many other lakes in the far West where an inexhaustible supply of commercial alkalies may be obtained at small cost. Mono lake, Cal., alone being estimated to hold over 78,000,000 tons of sodium carbonate.

Gold and Silver Bullion and Coinage.

It is worthy of note that the receipts of gold and silver bullion in this city have shown for some few years a gradual but steady increase. This is a certain indication that mining operations are generally being conducted successfully on this coast, and that our field is widening. Not only are new mines being opened, but old ones are being reworked in all directions. In this State the quartz mining interest was never in a more flourishing condition, and the increase of product from this source has about made up the deficit caused by the enforced cessation of hydraulic mining. Mines that 10 or 15 years ago could not be made to pay, under present industrial conditions are profitable. We have learned more about quartz mining than formerly, and many of our old extravagant habits and customs have been abandoned, and more economical methods adopted. The result of these changes is best shown in the increase of bullion receipts.

It is satisfactory to know also that the search for good quartz mines goes unceasingly on. All over the coast, every summer, the prospectors are at work in the mountains and hills. While there is less mining speculation than ever before, there is now legitimate investment in mining properties. People are buying mines to work them rather than to "stock" them. This working of mines instead of markets is having its legitimate result in the increased output of bullion.

It is somewhat curious that the mint in San Francisco has been for some time running mainly on \$5 and \$10 pieces, and, as we understand it, no \$20 pieces are being made. This is of course done under orders from Washington, but it results in great inconvenience to bankers and business men here. In receiving returns for bullion deposited, they are paid by the mint of officials in \$5 and \$10 pieces. In order to get the \$20 pieces it is necessary to go to the sub-treasury with the \$5 and \$10 pieces, and get them exchanged for "twenties." So great is this demand for the larger pieces that oftentimes those desiring them must wait at the sub-treasury until after banking hours to be waited on. How long this state of things will last is not known, but the sub-treasury is being filled up with \$5 and \$10 pieces, and being depleted of the double eagles very rapidly. It adds greatly to the duties of the officials of the sub-treasury, and is a great nuisance to the banks and business men.

In this connection as substantiating our assertions, we append a circular just issued by the Selby Smelting and Lead Company of this city.

OFFICE OF SELBY SMELTING AND LEAD COMPANY,
416 MONTGOMERY STREET,
SAN FRANCISCO, JUNE 15, 1886.

The U. S. Mint is now closed to the public for its annual cleanup, and as the impression has gained upon the minds of the people that the product of the precious metals on this coast has been decreasing, it is thought well to call attention to the fact that this is not the case, as proved by statistics published in the Bulletin of June 3, 1886, being extracts from Mint records of the gold coinage of the San Francisco Mint for the first eleven months of the last two fiscal years, which compare as follows:

	1884-85.	1885-86.
Double eagles.....	\$17,100,000	\$6,000,000
Eagles.....	790,000	6,350,000
Half eagles.....	1,027,500	12,990,000
Totals.....	\$18,917,500	\$25,340,000

For the corresponding period in 1883-84 the coinage was \$16,913,500, thus showing gradual increase each year.

This company has the only large gold and silver refinery on this coast outside of the U. S. Mint, and it may not be uninteresting to show from its records the extent of its gold business during the 12 months ending 31st May, 1886. There was deposited by us in the Mint in fine gold for coin as follows:

	1885.	1886.
June.....	\$ 922,400.12	January.....\$1,227,943.33
July.....	2,556,478.08	February.....1,021,839.73
August.....	1,199,822.62	March.....1,073,459.94
September.....	912,733.07	April.....1,178,272.82
October.....	1,187,960.94	May.....1,222,159.24
November.....	894,162.82	
December.....	1,320,476.79	
Total.....		\$14,813,862.50

From which it will appear that over one-half of the gold for coinage is supplied to the public through this establishment.

Our new refinery and smelting works at Vallejo Junction are now in full operation, and everything works to our entire satisfaction.

We have also made other important changes in our business which secure to us increased facilities, and by which we are enabled to serve the public more acceptably than heretofore.

Our charges are the same as the Mint.

We make returns in coin for gold deposits in 24 hours. We keep duplicate assay samples for six months, that parties may check our work at any time.

The extent of our business testifies the confidence which the public have in our work. Our records show correspondingly increased business in silver, base bullion and ores, the products of newly-discovered mines, and also of old mines being opened up at different points throughout the entire coast, all of which tends to the irrefragable conclusion which is shared by all who carefully study the statistics and developments being made, that the business of systematically working our mines has only just commenced, and that the future is full of promise. SELBY SMELTING AND LEAD CO.

Working Gold-Bearing Sulphurets.

Concentration and Chlorination in Nevada County, Cal.—No. 6.

(Written for the PRESS by C. A. SCHENK.)

The Chlorine Generators.

There are four chlorine generators, which are made of lead and are cylindrical in shape, 22 inches diameter and eight inches deep. They stand in a sheet iron pan, containing water, which pan again rests on brickwork, forming a flue and having a fire-place at one end; a stove-pipe at the opposite end leads off the smoke. By this means the generators can be heated to the temperature of boiling water, in case the evolution of the chlorine becomes too slow. The generating vats are provided with lead covers, having two openings, each six inches in diameter, into which lead pipes are luted with flour dough. One of these pipes serves for conducting off the gas, the other for introducing sulphuric acid. The second pipe is so bent as to form a trap just above the cover to prevent the escape of gas.

By means of a two-inch lead pipe, which in its lowest part is level with the bottom, the generator is cleaned and prepared for a new charge. For this purpose water is introduced by means of a hose, after taking off the cover, and the contents washed out into a trough. In taking off the cover the escaping gas becomes very offensive. To avoid this, generators of a more recent construction are provided with another two-inch hole in the cover, which is closed during the process of making gas and into which the rubber hose is inserted and water introduced, for the purpose of washing out the spent contents. The generators in use are not provided with stirrers.

Each Generator Is Charged

With nine pounds of black oxide of manganese and 11 pounds of common salt. The cover is then luted on with flour dough, and the sulphuric acid is run in; 16 quarts of commercial sulphuric acid, 66° B., are diluted with three quarts of water, and one-half of this solution is used for each generator. The acid is charged into a convenient lead vessel above the generator, and by means of a faucet is allowed to pass slowly through the trapped lead pipe into the same. Toward the end the evolution of the gas is assisted by fire. In this way the chlorine is slowly evolved at about the same rate that it can be absorbed by the ore in the tub. The gas does not enter the vat directly, but is first passed through a washbottle for the double purpose of holding back the small quantity of muriatic acid carried along with the chlorine, and of indicating by the more or less lively bubbling the right degree of absorption and evolution of gas. From the washbottle the chlorine passes through a rubber hose which at the other end is attached to the lead nipple under false bottom in the vat. The generator can be started as soon as the vat is half filled

with ore, as the filling will be completed before the gas can reach the top. As soon as the chlorine has risen to within a few inches of the surface, the cover is let down into its groove and luted. The space between cover and surface of ore must be well filled with gas to be sure of good chloridization. The gradual rise of the gas and any leaks in the apparatus where it might escape are easily detected by the aid of

another 24 hours before water is introduced. For this purpose the cover is raised at the Providence, and through a rubber hose with a floating board attached to its end the water led over the surface. The expelled chlorine escapes into the room. At the Merryfield chlorination works, in the same district, the cover is not raised for the introduction of the cold water. The cover in these latter works is provided with three holes; through one the water is introduced by means of a rubber hose; through the other, to which is also attached a rubber hose, the expelled gas is led out of the room; and by means of the third opening the

tated in these by a solution of sulphate of iron.

THE Virginia Chronicle says: The gravel deposit at the head of Little Valley, eight miles southwest of Franktown, is being thoroughly prospected by placer miners. After a heavy rain last winter two nuggets of coarse gold

FIG. 2. CROSS-SECTION OF CONDUIT.

FIG. 3. POSITION OF CONDUIT IN STREET, WITH WIRES READY FOR SERVICE.

were found, weighing half an ounce each. The only obstacle in the way of placer mining successfully on a small scale, in that vicinity, is the vast number of enormous boulders, too massive to move without the aid of powerful machinery.

CARSON MINT.—The Director of the Carson mint has addressed the Secretary of the Treasury suggesting the propriety of appropriating a sum equal to last year's appropriation, so that the operations may be resumed, especially in view of the fact that representations have been made to the mint bureau of the readiness on the

Teggart's Underground Conduit for Electric Wires.

The accompanying illustrations represent a recent invention of Mr. John Teggart, of San Francisco, for doing away with the unsightly telegraph poles which are becoming such serious obstructions and annoyances in all large cities.

Fig. 1 shows a vertical longitudinal section of the apparatus, with sheaves and cable intended for use in laying wires in the conduit. Fig. 2 represents an end view or cross section of the conduit, and Fig. 3 shows the position of conduit in the street with wires ready for service.

This conduit contemplates the utilizing of the curb, or it can be placed in any portion of the street. The advantages to be derived from a use of the curb are manifold, metal curbs, cast hollow with man-holes, *H*, at short intervals to afford easy access to any part of the lines, under the tapping of wires for new connections, a matter of much convenience and at minimum cost.

For the purpose of introducing wires into the conduit after it is in position, an endless cable, *E*, is placed within said conduit, supported by and passing over or around suitably grooved pulleys, *F*, which are journaled upon the side wall. By attaching a wire to this endless cable and connecting the reel, *G*, with one of the pulleys operating the cable, the wire can be introduced for any desired distance into the conduit, and with greater ease and more speed than can be accomplished where poles are in service.

The standards, *B*, support the cross-bars, *C*, within the conduit. By means of numbers placed upon the respective insulators on the cross-bars, the wires can be easily designated so as to make or sever connection, at any given point on the line, with any particular wire. Where telephone connection is desired it would be only necessary to remove the cap from one of the man-holes and connect with the desired wire in the simplest manner possible.

Electricians of prominence and acknowledged authority in such matters have examined Mr. Teggart's invention, and pronounced it practicable in every detail and of a very high order of merit. Much consideration is due to this system of conduit.

In the city of New York, where the question of removing electric wires from poles is a neces-

FIG. 1. LONGITUDINAL SECTION OF TEGGART'S UNDERGROUND CONDUIT FOR ELECTRIC WIRES.

gradual rise of the water is measured. The injurious effects of the expelled chlorine on the health of the workmen are avoided. As soon as the vat is filled with water the cover is raised and the wooden discharge faucet opened, from which the solution flows into the precipitation tank. These are of the same size as the chlorination vats, only a little shallower and without a false bottom. The gold is precipi-

part of the producers of bullion to deposit the same at the mint at Carson, instead of sending it to private refiners.

SYCAMORE, that has been useful simply for cigar boxes, comes into fashion for an inside house finish in place of cherry, ash, maple and walnut, and good quarter-cut boards are worth \$50 a thousand,

sity, the underground conduit has demanded much attention, but as yet, so far as we can learn, nothing has been presented equaling Mr. Teggart's system, either in simplicity or utility.

THE Bodie mill is about to cease crushing ore for the Mono Company, and will probably start on Bodie ore in a short time.

MECHANICAL PROGRESS.

American vs. English Steel.

A correspondent of the *Chronicle*, of this city, recently visited several large steel-ware manufactories at the East, with the view of learning whether the best steel was made in this country or imported from Europe. One manufacturer led the way into a long room full of wheels and forges, and walking up to a pile of flat bars, something like thick hoop iron, chose two.

"Here," said he, "are two bars of steel, one of the best English and one of the best American make. Now watch what I am about to do."

The two bars were thrust into a heat of live coke, and held there until both assumed a cherry redness, and then were both plunged into a tub of cold water. Then an end of each was laid on an anvil, a sharp blow was given with a hammer and a corner from each was snapped off.

"Now look at the broken edge and tell me what you see," said this cutler.

"What I see," said the reporter, "is that the broken part looks like the loveliest French gray silk. The grain in each is heartily fine, as though it were a mass of the most beautiful crystals."

"Do you see any difference in the grain of the two?" persisted the cutler.

"Scarcely," was the reply, "and yet I should say that this is a trifle the finer."

"The one you have indicated is American steel," said the cutler. "Now here is another test. Bend a knife-blade, Jim," he said to a workman. The man took a rough but tempered blade from a pile before him, thrust it in a handvice, and leaning his tip on the anvil it bent into a hoop, only to fly back straight again when released. "That's American steel," said the cutler. "Now come upstairs, and I'll show you another test."

In the upstairs rooms a row of men sat behind a row of giant grindstones, grinding razor blades.

"Have you any difficulty putting an edge on these?" asked the cutler of the foreman. "None." "Do they hold the edges?" "Admirably." "Do they hone well?" "Easiest in the world."

"These," said this cutler, "are made of American steel, and I don't think I can answer your question any better. The best steel in the world to-day," he went on, "is the best American steel, and the best cutlery in the world is that which is made out of American steel. Yes, sir, and the best steel workmen to-day are the Americans. Why, when we get an English worker bers with his ability only to do a single class of work, he can't earn his salt until he has learned American ways." In reply to a question as to what proportion of English-made cutlery is imported to-day compared with what was imported five years ago, the reply was as follows:

"That is something outside of my line. I only know that the belief in English cutlery leading the world has gone out of fashion. Not very long ago you had to show imported goods in order to make sales; now the conditions are reversed, and American goods—especially razors, carvers and scissors—receive the preference. The only thing in which we cannot as yet compete successfully with England is the pocket cutlery. But this explanation of that is simple enough. A pen-knife, as you will see, is made up of a number of pieces. There are the tips, the rivets, the plate, the spring, the horn of pearl for the handles, and so on. The English manufacturer gives these pieces out, and the whole family of a workman is employed at some working them into shape at starvation wages. We haven't come to that yet, and I hope we never shall, and until American machinery takes the place of these poor people toiling in their hovels, England is welcome to her monopoly of pocket knives."

"American steel," said another cutler, "is making almost daily progress, and certainly American cutlery in many respects is unequalled. There are many conservative people yet who imagine it is the correct thing to have English knives and forks on their tables, but that idea is rapidly dying out. There is no razor so good as an American razor, of which there are now hundreds of first-class brands, while the American scissors and shears have actually driven the English article out of the market. The American brand on most cutlery now is in fact the selling one."

THE FUTURE OF MACHINERY.—To a representative of a past epoch, says the *American Machinist*, the new applications of machinery and the new methods of manufacture are a revelation, but there are stranger things in store for their successors now coming upon the stage of action. There is yet a vast reserve of mechanical skill to draw upon and the inventive genius of the age is only just beginning to be developed. The skillful machinist of to-day may seem a veritable ignoramus in the eyes of posterity, and the man of the next century will undoubtedly find much in the changes of a single generation to challenge his astonishment and defy his comprehension. We of the present do not realize that a boundless field of discovery is opening up to us and that new explorations are being and will be made. Thus at every step we shall find new and better, shorter and cheaper methods, and that certain principles and devices are capable of being indefinitely

extended. Though past achievements border upon the marvelous, they are but the alphabet to the possibilities of the future.

Welding Iron and Steel.

A series of experiments were recently undertaken by Prof. J. Bauschinger, an English engineer, at the instance of an engineering firm. Similar experiments had previously been made at the Royal Technical Experimental Institute, at Berlin, and by Mr. W. Hupfeld, at Prevali, which gave very different results, those at Berlin being very unfavorable; those at Prevali very favorable, as regarding the welding capacity of steel. Prof. Bauschinger recapitulates the main results of these tests before describing those made by himself. The test pieces were flat, round and square in sections, the largest being 3.149 by 1.181 inches. Each piece was cut in two cold, swelled up on the anvil, when hot, 0.196 to 0.392 inch, and after heating to the proper degree, the two pieces were laid on each other and welded together by hand or steam hammer. Some preliminary studies were made in the laboratory of this college to ascertain the best method for welding and the best flux for steel; a pure coal fire was used.

In the chief experiment the steam hammer was employed. Every piece after welding was tested in the usual way for tensile strength, the limit of elasticity, contraction, extension and ultimate strength being determined, the same quantities having been measured for pieces of exactly similar quality, section and length, but without a weld. The limit of elasticity in both steel and iron is nearly always reduced by welding, and this is, without exception, the case as regards the extension; the contraction of welded is less than that of unwelded pieces when the fracture takes place in the welded portion. The general conclusions arrived at are that for steel the best welding temperature is just at the transition from a red to a white heat; a quick fire and smart handling are necessary, as the pieces should not be long in the fire.

Analyses were made of three samples, one of which welded admirably, the second badly, and the third not at all. Professor Bauschinger is of the opinion that in the case of mild steels, such as those tested, with a low carbon, intended to take the place of bar iron, success or otherwise in welding depends less on the chemical composition than on the chemical treatment.

In this connection we may refer to a paper recently read before the English Institution of Naval Engineers by Mr. Parris, in which, speaking of the different kinds of welds, he gave the preference for heavy work to the scarf weld and considered the long V weld as the next best. He submitted some large specimens of welds made by the use of sledgehammers, screws and the steam hammer. Upon trial all of the welds broke at red heat by being bent, except the one made under the steam hammer, which was repeatedly bent forward and back till black hot and then broke elsewhere than at the weld.

A NEW MATERIAL FOR RAILROAD TIES.—A new and very important application of ozokerite has been recently discovered in Russia; it is now used for making ties in the Transcaspian Railroad, which has already passed Oschatat and nearly reached Merv. The process of manufacture is very simple and inexpensive. Kyr, the local name for ozokerite, is found there in thin layers of 7-in. thickness. In its primitive state it contains a certain percentage of decayed matter. To remove this the ozokerite is melted in large caldrons, the refuse sinks to the bottom, and the pure ozokerite collects at the top. This purified ozokerite, melted and mixed with 75 per cent of limestone and 25 per cent of fine gravel, gives a very good asphalt, which is pressed in boxes shaped like railroad ties. Notwithstanding the high temperature, which reaches 48° R. (140° F.), the ties retain their shape and hardness. These asphalt ties are used all along the road, except at the ends and center of every rail, where as yet wooden ties are employed. In this way about \$800 per mile is economized.

DOES THE PISTON COME TO A STANDSTILL?—At the last meeting of the Engineers' Club of Philadelphia, Mr. Collins offered the following interesting mathematical conundrum: "Does a locomotive piston at the end of each stroke, in reversing its direction, come to a standstill, and if so, can the same be mathematically demonstrated? Also, would a difference in speed affect the duration of its stationary condition, if such exists?" Mr. Collins added: "As the crank pin describes a circle, changing at every point its direction, and therefore having at all times more or less lateral movement, and its movement being continuous, it is argued that the piston can have no movement of rest without the crank pin coming to rest also, supposing perfect joints." Yet this much controverted question is still open for debate—among cranks.

INCREASED ACCURACY IN MEASURING.—The common use in machine shops of measuring instruments of much greater precision than were used ten years ago is one of the signs of improvement. Men who then looked upon micrometers as curiosities now use them daily, much as they formerly used a pair of calipers. This is in part due to the fact that fine measuring tools are now furnished at reasonable cost, but mainly owing to the fact that the demand is for better and different work. Fits are made to measure, and sizes maintained in a way not thought possible a few years ago.

SCIENTIFIC PROGRESS.

Copper in Vegetable and Animal Organisms.

The discussions and complaints growing out of this very reprehensible custom in practice of coloring pickles and canned vegetables by the use of copper, and the numerous lawsuits growing out of the same, have called for numerous analyses to ascertain the extent of the adulteration, and lead to somewhat exhaustive researches which have shown that both vegetable and animal organizations contain naturally a perceptible amount of copper in the form of salts of that metal. Careful analyses show that this amount varies from two-one hundredths of one part in one million to 14 parts in one million. The lesser amount is found in turnips; the larger in wheat bran. Wheat itself contains from four to 10.8 parts, varying, probably, according to the soil upon which it is grown. Barley contains about the same amount. Rice has been found to contain from 1.15 to 6.13 parts and potatoes 2.8. A correspondent of the *American Grocer* gives some further interesting information in this direction, from which we collate as follows:

Odling and Dupre detected copper in 43 different cereals and roots used as food, and in 21 out of 23 samples of flour-bread. It is now universally conceded that copper is present in all vegetables and cereals grown in a soil containing its salts.

These facts show that the question of fraudulent or improper addition of copper to food products turns not on its mere presence, but upon the amount present. Dupre, who has made deep researches in this direction, states that the presence of copper in food in greater proportion than one part per 100,000, indicates that the copper has been added by man, either accidentally or designedly.

The question naturally arises, "What is an injurious amount of copper?" The medicinal dose of copper sulphate, which is the only salt of the metal used for internal medication, is, according to the "United States Dispensatory," of copper sulphate, as tonic or astringent, one-fourth grain, equivalent to .0636 grains of metallic copper. The dose, as an emetic, is from 2 to 5 grains, equivalent to .509 to 1.27 grains.

Medical men generally concede that pure metallic copper is not poisonous. Opinion concerning the poisonous qualities of its salts is divided, but the bulk of opinion seems to be on the side which avers that it is. It is in this form of salts that the metal is present in canned vegetables. The peculiar fact has been brought out by analysis that pickles contain more copper than the liquor in which they are immersed, and some individual pickles contain more than others in the same vessel. This probably arises from the way in which the copper is added—immersing a copper plate in the vat containing the pickles in mass; the pickles nearest the plate receive a larger amount of the metal than those further off. The same would be true of other vegetables so treated.

Copper in the Animal Kingdom.

Copper is also found in the tissues of the higher animals, where its presence is probably accidental, though cases where it has been detected in lower types of animal life have led observers to express the opinion that it is an essential constituent. Eminent chemists have made quite exhaustive analyses and furnished tabular results from which the following is summarized:

In 12 human bodies out of 14, submitted to analyses, the amount of copper in grams averaged from 0.011 to 0.023. The liver contained a much larger proportion than the whole body. The spleen of a man averaged about 0.0617; that of woman 0.0473. Copper has also been found in the kidneys, in the intestines and other isolated parts of the body, and in the blood.

THE USE OF ZINC IN BUILDING.—The extensive outdoor use of zinc by builders at the present time has directed attention to the peculiar process of oxidation which this metal undergoes, and which is so important to be considered in all applications involving exposure. The rusted surface does not rub off or blow away, but forms a sort of hard crust or enamel upon the surface of the metal, and when laid upon boarding which is or may become damp or exposed to steam or condensation below, it rusts on both sides. The thin zincs first introduced in this way were rusted through, brittleness ensuing and failure being the result. But if the zinc be of sufficient thickness, after a certain time oxidation ceases, and the result is a body of solid, sound metal, incased above and below by a solid coating, thoroughly impermeable to the accidents of weather or temperature, and which requires no painting. The various ways of spreading zinc consist mainly in laying it in a corrugated form, without hoarding, the trusses of iron or wood of the roof carrying the weight, or in rafters about one foot, more or less, apart, with a corrugation at each rafter only, or upon a general surface of hoarding, in the manner of a lead flat.

HOW INCANDESCENCE IS PRODUCED.—Incandescence is a white heat, or the glowing whiteness of a body caused by intense heat. The little glass bulbs, says an exchange, with their brilliant horseshoe of glowing filament, attract no more attention than the flickering gas jet,

But the facts about the gas jet are easily and generally understood, while the electric lamp is still a puzzle to many people. Both produce light by incandescence. The molecules of gas are rendered incandescent by the heat generated by the combustion of other molecules. The blue portion of every gas flame is where combustion is taking place, and from there comes the heat which keeps the rest in a state of incandescence. With the electric lamp it is the heat produced by the friction of an electric current compelled to go through a fine carbon filament, which raises that filament to a condition of incandescence and produces light.

AURORA SOUNDS.—In March, 1885, Sophus Tromholt dispatched some thousand circulars to all parts of Norway containing different queries regarding the aurora, and among them also the following: "Have you or your acquaintances ever heard any sound during aurora, and, in this case, when and in what manner?" Up to September 16th, he had received answers to these queries from 144 persons. Of these not less than 92, or 64 per cent, believe in the existence of the aurora-sound, and 53 (36 per cent) state that they have heard it themselves, while the other 39 cite testimonials from other people; only 21 (15 per cent) declare that they have never heard the sound and know nothing about it, and the other 31 (22 per cent) have not noticed this query at all. There are thus 92 affirmations against 21 negations. The sound is variously described in these answers as sizzling, creaking, whizzing, rustling, crackling, hissing, whispering, rushing, buzzing, rippling, roaring, din, breezy, whipping, fanning, clashing, flapping, sweeping, etc. —*Nature*.

STOCK AND GRAFT.—Some observations have been made by Strashurger recently on the reciprocal influence of stock and graft, and on the limits within which plants that are specifically distinct will permit of grafting or budding. He succeeded in grafting *Datura Stramonium* on *Solanum tuberosum*. The resulting plant produced good-sized tubers which contained a small quantity of atropine. But what is still more remarkable, he successfully grafted *Schizanthus Grahami* on *Solanum*, these plants belonging to distinct natural orders, the former to the Scrophulariaceae and the latter to the Solanaceae. It is the first instance on record where a union of this kind has been accomplished between plants so remote in their relationship. A novelty in horticulture in California is the successful grafting of Italian chestnuts on the ordinary black oak. It has been practiced with the best results in a number of instances in the Napa valley.

THE FOOT OF A HORSE.—The foot of a horse is one of the most ingenious and unexampled pieces of mechanism in animal structure. The hoof contains a series of vertical and thin laminae of horn, amounting to about 500, and forming a complete lining to it. In this are fitted as many laminae belonging to the coffin-bone, while both sets are elastic and adherent. The edges of a quire of paper inserted leaf by leaf into another will convey a sufficient idea of the arrangement. Thus the weight of this animal is supported by as many elastic springs as there are laminae in all the feet, amounting to about 4000, distributed in the most secure manner, since every spring is acted on in an oblique direction.

THE WORLD MUST MOVE.—In 1877 electric lighting by the incandescent system was declared by many to be contrary to scientific principles. The same was said of the use of iron, and later of steel, in bridge building. The Suez canal was once denounced as a wild and foolish scheme. Less than 50 years ago educated mechanics asserted that steamships could never carry enough coal for a long ocean voyage. Leading ship-builders told us that iron ships could not swim, and when one or two floated it was said that they would not hold together permanently. Rolls for flour making were once hooted and derided. The world will not stand still for any one.

SPIDERS AND FORESTS.—Dr. C. Keller, of Zurich, claims that spiders perform an important part in the preservation of forests, by defending the trees against the depredation of aphides and insects. He has examined a great many spiders, both in their viscera and by feeding them in captivity, and has found them to be voracious destroyers of these pests; and he believes that the spiders to a particular forest do more effective work of this kind than all the insect-eating birds that inhabit it. He has verified his views by observations on coniferous trees, a few broad-leaved trees, and apple trees.

GAS AND ELECTRICITY.—Experiments have proven that gas will furnish more light when used to drive an electric motor than when used directly as an illuminant. In a paper recently read before the Kings College Engineering Society of London, it was mentioned as the result of many experiments that 1000 feet of gas used to produce incandescent electric lighting by means of a gas engine would give twice as much light as it would if employed as an illuminant in the ordinary way.

ELECTRIC LIGHTING BY INDUCTION.—On the British ship *Colossus*, belonging to the navy, electric hand-lamps are in use. They have no external connections but act by induction.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

BICYCLE SADDLE.—John Payne, S. F. No. 342,925. Dated June 1, 1886. This new saddle is intended to allow great freedom of movement and to admit of perfect adjustment to varying weights and conditions. It consists of a flexible suspension saddle, the front end of which is connected with a lever or levers turning upon a journal-pin fixed to the neck of the machine and the rear end connected to the upper end of similar levers fulcrumed upon a standard which is fixed to the back-bone of the machine. The lower ends of the front and rear levers are united by longitudinally working springs having both a vertical and a longitudinal adjustment by which the action of the saddle and the degree of tension may be regulated.

LIFE-RAFT.—C. J. Ifendry, assignor to Leduc Tule Improvement Co., S. F. No. 343,028. Dated June 1, 1886. In making life-rafts it is customary to unite two or more hollow, air-tight cylinders by a framework, which maintains them on a plane side by side, but these often become broken, perforated and useless in time of need. In making this new raft, the inventor takes the round and pithy stock of the reed known as the "tule," so abundant in California, which is extremely light and buoyant, and from its cellular structure does not become water-soaked and heavy, and he binds them together in cylindrical masses of sufficient diameter, the cylinders being from five to thirty feet in length. These reed cylinders are then covered with canvas, which is painted. The ends are protected by metallic caps. Suitable framework and straps form a hindering medium to make the raft in the desired shape.

TRANSFER APPARATUS FOR SAWMILLS.—Geo. W. Loggie, Portland, Or. No. 342,918. Dated June 1, 1886. This is an apparatus for transferring lumber in sawmills or on iron rails or other transfer work. It consists of stationary skids or timbers upon which the cant or lumber falls after passing the saw, the skids extending transversely to the line of the cant, a series of parallel skids mounted so as to oscillate about double centers or fulcrums, and a mechanism whereby one end or the other may be raised above its fulcrum at will. In combination with these movable levers skids are traveling chains so arranged that when the skids and chains are raised about the stationary skids, the timber will be carried upon them from one side to a point beyond the center, and from this point may be carried by raising the opposite end to the point of delivery. This apparatus is specially useful in mills where the logs are first sawed into large pieces called "cants," which must afterward be reassembled by a second sawing apparatus, and it is placed in such a position that after the log has passed the saw the cant may fall directly upon this apparatus, and by raising that end of the chains or skids the cant will lie upon them, and thus be carried across to a point more than half way, or beyond the center, where it can be taken up by raising the opposite ends of the chain skids and carried the remainder of the distance across to the opposite side.

Leadville's Bullion Yield.

Leadville is turning out considerable high grade bullion and also keeping the gross production in advance of last year's product. Considering the many disadvantages experienced by both miners and smelters, the yield of bullion thus far this year has been surprising. The *Herald-Democrat* makes a comparison for the first four months of the present year with 1885, which shows a gain of nearly 900 tons, as follows:

	1885.	1886.
January (tons of bullion).....	2,050	1,103
February (tons of bullion).....	1,035	2,482
March (tons of bullion).....	2,175	1,630
April (tons of bullion).....	1,665	1,280
Total.....	7,975	6,693

Gain for 1886, 881 tons.

The value per ton of the bullion shipped could not be ascertained, but it is unquestionably greater than it was last year, as the ore is averaging far better. Another feature calculated to improve the average silver and gold contents of Leadville base bullion are the desilvering furnaces, erected lately at the Elgin, La Plata and American smelters. By this innovation a large portion of the furnace production of the smelters is desilvered, and the bars of lead sent out caused to contain two to five times as much silver and gold as the original pigs of lead did on coming from the smelting furnaces. Not only have the shipments of bullion been fair this year, but the amount of ore shipped to the valley smelters has increased, and the indications now are that Leadville will send out more lead and precious metals than at any time in the past.

THE new leads on Mosquito creek, Cassiar, which were struck by the miners who remained and prosecuted the tunneling during the winter, are said to be of very rich indications, and something like a new rush to that camp seems probable.

USEFUL INFORMATION.

"LA NATURE" claims that a machine of one-horse power would keep 27,000,000 watches running.

TO REMOVE VARNISH without injuring paint, brush on spirits of ammonia or hartshorn, which softens the oil, allowing of its being rubbed off easily.

FILING BAND SAWS.—The use of a rounded file is recommended for filing hand saws to prevent sharp angles, a common cause of breaking.

A HOT MIXTURE of one-third paraffine and two-thirds gutta percha, forced into the pores of wood, is winning favor as a means of preventing decay.

IT IS NOW recommended to nail shingles intended for a roof in a solution of lime and salt. It is claimed that it adds a good many years to the usefulness of the shingle—by preventing them from decaying.

TO FASTEN ON LAMP TOPS.—A very good cement to fasten on lamp tops is melted alum. Use as soon as melted, and the lamp is ready for use as soon as the cement is cold. Plaster of Paris is generally used for that purpose.

TEMPERING MAINSPRINGS FOR GUNS.—Heat the spring to a good red and plunge it in the water, then take a fat pine splinter and smoke the spring well all over; next heat it until the smoke burns off; then dip the spring in the water.

A SUBSTITUTE FOR OIL IN DRILLING.—A very superior mixture may be made as follows: Take spirits of turpentine and put into it as much camphor gum as it will dissolve. With this composition there will be no trouble in drilling anything hard.

BLACKBOARD COMPOSITION.—Make a thin paste of lampblack and flour emery with shellac varnish, and apply the same to the wall or board to be coated. Should the mixture be too thick, it may be thinned down to the right consistency by adding alcohol.

HARMONY OF COLORS.—Red looks well with black, white or yellow; blue harmonizes with white or yellow; green, with white, black or yellow; gold, with black or brown. White appears well with any color. Purple, pink and white harmonize beautifully.

FRUIT STAINS upon cloth or upon the hands may be removed by rubbing them with the juice of ripe tomatoes. If applied immediately, powdered starch will also take stains out of table linen. Left on the spot a few hours it absorbs every trace of the stain.

PIPE CLAY made into a paste with cold water will, it is said, remove grease stains from papered or plastered walls if put on without rubbing, let stay over night, and then brushed off lightly. Where the grease has been on for some time several applications may be needed.

KEEPING COAL.—It is not generally known that coal is less valuable for having long remained in store perfectly dry. Most coal mines are saturated with water, and if the water is drained off the coal becomes flinty and valueless. Coal stored through the summer should be sprinkled and kept moist.

TO PREVENT THE CRACKING of wooden fan-cets, etc., put the articles in melting paraffine, and heat them there at a temperature of 212 degrees F., until bubbles of air cease to escape from the wood. The whole is then allowed to cool to about 120 degrees F., when the wood is taken from the bath and cleaned from the adhering paraffine by rubbing with a dry piece of cloth.

SPOTS ON BRASS.—Sulphuric acid will remove spots from brass that will not yield to oxalic acid. It may be applied with a brush, but great care must be taken that no drop of the acid shall come in contact with clothes or skin, as it is ruinous to garments and cuticle. Bath brick or rotten-stone may be used for polishing, the latter being preferable for delicate work.

FOR A RUST JOINT.—For making a rust joint that will bear heat, cold and rough usage, the following formula has been highly recommended: Ten parts iron filings, three parts chloride of lime, and enough water to make into paste. Put the mixture in between the pieces to be joined and bolt them together, leaving until dry. After 12 hours the cement has been known to break off the solid iron.

TO PRESERVE MILK INDEFINITELY.—Pour the milk into a bottle and place the vessel up to its neck in a saucenpanful of water, which is then to be put on the fire and allowed to boil for a quarter of an hour. The bottle is now to be removed from the water and carefully closed with a good and tight-fitting cork, so as to render it as air-tight as possible. Milk which has been preserved by this process has been kept for more than a year without turning sour. Milk may also be preserved by putting a table-

spoonful of horseradish, scraped in shreds, into a panful of milk. When milk thus treated is kept in a cool place it will be found to keep good for several days, even in hot weather.

ARTIFICIAL SPONGE made of cotton, rendered absorbent and treated with antiseptics, has been invented in England. A piece of the size of a walnut has absorbed water until it reached the size of a cocoanut. It is so cheap that it need be used but once.

CONVENIENT WAY OF WATERPROOFING CLOTH.—It is found that when paraffine is thoroughly mixed with linseed oil, cast into small blocks, and cooled, it may be used to make any fabric, as cloth, felt and leather, waterproof, by rubbing it with such a block, and ironing afterward to equalize the distribution of the material in the pores. If too much is not put on, the material may be made to be only impervious to water, but not to air, the small greasy pores repelling water, but not air.

KRUPP'S GUNS.—Advices from Constantinople would make it appear that the cannon made by Krupp for the Turkish Government are not of the best. It is stated that a series of experiments have been in progress in the Dardanelles to test the merits of several of the new Krupp guns; that several have burst, killing a number of gunners, and that a number of guns have been found to be worthless. It is added that attempts have been made to keep these disasters secret, but without avail.

GREASING BELTS.—Some one writes: "I noticed an engineer the other day doctoring a belt to prevent its slipping by pouring grease on it and then fine resin to cover it all. If I had been his employer I would have told him how to do better, and a repetition would have brought him his walking papers. It costs a great deal to buy belts to be used that way, for they would be short-lived. Good neatfoot or castor oil applied to belts occasionally Saturday nights is good treatment, but such treatment as the above is very injurious to a belt."

MILK SUGAR.—The extraction of milk sugar from whey is a comparatively new industry. In Burlington, Vt., a company was organized and a factory built, last summer, for the purpose. Contracts have been made with a number of farmers in the vicinity sending milk to the cheese factories to furnish the company all their whey for five years. The demand for the sugar is so great that contracts are now being made by Prof. Sabin, of the State University of Vermont, with western farmers for larger supplies of whey than are readily obtained from small New England factories.—*Ex.*

GOOD HEALTH.

A Victim of the Cigarette.

Woerishoffer, the dead speculator, will live in history as one of the most brilliant and daring of the Wall-street millionaires. Like Gould, he began life in poverty. He started as an office boy, developed into a clerk, and finally blossomed out as a speculator. For 20 years this man has been engaged in the heaviest financial battles of modern times. The capitalists of the metropolis recognized his generalship and looked up to him as a leader. He was a hard fighter, and he was generally successful. It is passing strange that such a man, gifted with a superb will-power, should have been slain in the most inglorious of conflicts and vanquished by the puniest of antagonists. This Colossus met his fate when he tackled the cigarette. A brief history of the struggle may serve to point a moral and convey a warning. Woerishoffer gradually drifted into the habit of inveterate smoking. He smoked 50 cigarettes a day. He kept it up for 15 years, inhaling the smoke all the time. Years ago Woerishoffer saw danger ahead. His head, heart, stomach and nerves remonstrated, protested and begged him to change his course. In their agony they cried out against the fiendish cigarette, and denounced it. Colossus grinned sardonically. When he got ready he would down the cigarette and not before. Slowly but surely the coils of smoke twined around their victim, and tightened their grip each day. The man's heart turned into a big sponge saturated with nicotine. Still the smoker continued the fight. He would lie down when too feeble to stand, and smoke, while his heart beat at the rate of 120 a minute. He said: "I have a German stomach, an American head; I am equal to anything." At last he became alarmed. To his horror and amazement he found that he could not give up the cigarette. He tried time and again. He went to a famous medical man and said: "You shall have \$50,000 in gold if you will emancipate me from the cigarette." The physician worked hard, but it was no go. The big, strong man, the giant who tossed money-kings about like babies, lay hopelessly crushed under a little rice-paper pigmy. "A remarkable case," the medical men say. Very; but there will be others like it.

The above, from the *Atlanta Constitution*, conveys a most impressive lesson, which ought to be brought home to every inveterate smoker, and, for that, to every young beginner in the use of the cigarette or cigar. How many hundreds of our young boys are now walking the streets of this city picking up and smoking

castaway cigarettes and cigar stumps—the disgusting practice—who will yet live to see the day that they will rue the time when they first commenced the practice of smoking. The rapid increase of this habit bids fair to soon rival that of the intemperance use of ardent spirits. The Germans are the most inveterate smokers in the world, but the Government of that country is already taking measures to curtail it, especially among the young. It is positively interdicted among the newcomers into the military service, while under the direct control of its officers, and that includes several years' service from every able-bodied man in the nation. It is high time that some measures were taken in this country with the same object in view.

The Great Question of the Day.

The late Dr. Samuel D. Gross, the father of American surgery, used the following words in an address delivered at the dedication of the McDowell monument:

"Young men of America, listen to the voice of one who has grown old in his profession, and who will probably never address you again, as he utters a parting word of advice.

"The great question of the day is not this operation or that, not ovariotomy or lithotomy, or a hip joint amputation, which have reflected so much glory upon American medicine, but preventive medicine, the hygiene of our persons, our dwellings, our streets—in a word, our surroundings, whatever or wherever they may be, whether in city, town, hamlet or country, and the establishment of efficient town and State boards of health, through whose agency we shall be more able to prevent the origin and fatal effects of what are known as the zymotic or preventable diseases which carry so much woe and sorrow into our families, and often sweep like hurricanes over the earth, destroying millions of human lives in an incredibly short time.

"The day has arrived when the people must be aroused to a deeper and more earnest sense of the people's welfare, and suitable measures adopted for the protection as well as for the better development of their physical, moral and intellectual powers. This is the great problem of the day, the question which you, as the representatives of the rising generation of physicians, should urge, in season and out of season, upon the attention of your fellow-citizens; the question which, above and beyond all others, should engage your most serious thoughts, and elicit your most earnest co-operation.

"When this great object shall be attained; when man shall be able to prevent disease, and to reach, with little or no suffering, his three-score years and ten, so graphically described by the Psalmist, then, and not until then, will the world be a paradise."

HEALTHY EMPLOYMENTS.—An Italian doctor has lately asserted that the workmen in borax factories appear to possess a charm against the attacks of cholera. During the terrible epidemic of 1864-65 the workmen in seven contiguous factories in Italy were quite free from the disease, which killed off one-third of the population of a village in the immediate neighborhood. He recommends the internal administration of borax as a specific for cholera in doses of five grains (77 grains) each day. He believes that it not only destroys the microbes in the intestinal canal, but also in the blood. The doctors, on the authority of the *Atlanta Constitution*, say that tobacco manufacture of all kinds, both the preparation of the raw material and its manufacture into cigars and cigarettes, is the healthiest business in the world. In the latter branch, while the work is largely done by girls, it is said the employees are seldom sick, and present a marked contrast with girls employed in cotton factories. We wish as much could be said of the consumption of tobacco.

FOOD AND CONSCIENCE.—Never go to bed in any danger of being hungry. People are kept awake by hunger quite as much as by a bad conscience. Remembering that sleep is the essential force which the whole scheme starts, decline tea or coffee within the last six hours before going to bed. If the womenkind insist, you may have your milk and water at the tea-table covered with tea; but the less the better. Avoid all mathematics or intricate study of any sort in the last six hours. This is the stuff dreams are made of, and hot heads, and the nuisances of waking hours. Keep your conscience clear. Remember that because the work of life is infinite, you cannot do the whole of it in any limited period of time, and that therefore you may just as well leave off in one place as another.—*Edward Everett Hale.*

THE DYING.—A leading physician says that a patient who is lying dying of exhaustion is generally dying of starvation. We give him beef tea, calf's-foot jelly, seltzer and milk—that is, a small quantity of the sugar of milk and some fat; but the jelly is the poorest sort of food, and the beef tea is a mere stimulant. The popular belief that beef tea contains "the very strength of the meat" is a terrible error; it has no food value.

SEAT OF PAIN.—Pain, the *Scientific American* says, is chiefly mental, and the severity of it would be comparatively slight did we not give ourselves up to it. Animals suffer less than men. A horse will feed after breaking a leg, while a man would lie and moan.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

RESUMED CRUSHING.—Amador Ledger, June 12: The Amador Queen mill resumed crushing on Tuesday, after 10 days' idleness, caused by the breaking of one of the jaws of the ore-crusher. The Zeile mill was started again early in the week. The hole in the reservoir occurred in the vicinity of the pipe, and was caused, it is supposed, by a defect in the laying of the pipe, and not on account of any weakness of the banks. About 100 feet of pipe collapsed when the reservoir broke, and this was the cause of the stoppage of the mill. The work of putting in the new pump is progressing at the Downs mine. They expect to commence sinking about the first of next month.

SUTTER CREEK.—The Lincoln mine is running along at the usual gait; the employees are to be paid off this week. The work of hauling the 10-stamp mill from Angels, Calaveras county, to the Iowa mine here is almost finished. Only one load more remains to be hauled. The work of putting up the mill will commence forthwith. There are no new developments to report in connection with the Eureka, except that the men are busily engaged in putting the new air compressor in place.

Calaveras.

INDIAN CREEK.—Mt. Echo, June 9: The Woods mine is at the present mining some very valuable ore. The dump is constantly filled with the gold-bearing rock so famous in this section. A large force of men will be placed on duty as soon as the necessary milling preparations are made, and a vigorous "boom" will follow. The richest ore extracted in Indian Creek for many years is being stopped at present. The next yield bids fair as crowning all previous productions. The Calaveras mine is making good progress. Stopping is being carried on vigorously in the western stopes where some very rich ore has recently been discovered. The mill has been kept in constant motion and the batteries make a wonderful showing. All seems to be life and activity at the Calaveras at present. A very handsome cleanup was made last Sunday, in fact, the best for many months. The Bean mine, owned and controlled by Mr. James Bean, is pushing forward in a systematic manner. A well-defined ledge of three feet is displayed in the shaft, to which a tunnel now 150 feet in length is being run to tap the main body, and which is at present within a few feet of its destination. The Sature mine, situated a short distance from Murphey's, is making a magnificent display of fine-paying ore, immense in quantity and rich in quality. This mine was recently bonded for \$50,000 to a Boston company and will be accepted the 1st of June. The property is a very valuable one, and the present owner is Mr. John Sature. The Kelley mine, which for some time past has been worked on a real systematic scale, has been accepted at the figure asked by the proprietors. The sum is \$100,000. Indian Creek as a quartz-mining center cannot be equaled elsewhere in the State. Its mines are constantly pouring forth its auriferous yields in abundance and making good returns to its proprietors.

Inyo.

THE COLDWATER MILL.—Inyo Register, June 10: A correspondent informs us that the failure of the old Sacramento mill, recently put up in Coldwater canyon, is only partial, due in part to the bursting of the water pipe. The pipe put in is too light for the 180-foot pressure put upon it. Mr. Melvin, the builder, intends to change about 200 feet for heavier cast-iron pipe. Mr. La Grange, superintendent of the Casey mine, has a mule-train packing ore to the mill. A small force of men are now at work in the mine.

Napa.

ÆTNA MINES.—Napa Register, June 9: While in Pope Valley the other day we took a run up to the mines—the Washington and Star—which now come under the general name of "Ætina." We found the superintendent, M. G. Rhodes, who is also one of the owners, in his office, on the site of the old Phoenix mine, and with him inspected the Star mine, near by. After going over the surface we donned a miner's suit, boarded the cage and went by way of the main shaft to the tunnels, crosscuts, stopes, etc., 375 feet below. The coarse ore is smelted at the furnace located just below the mine and the finer stuff is conveyed by car over a tramway to the furnace at the Washington mine, over half a mile away. Though these mines yield low-grade ore, they pay well under the able management of Mr. Rhodes, the Ætina being one of the five quicksilver mines now in the State that are producing. Seventy men are employed and 350 flasks of mercury is the average monthly shipment.

Nevada.

PITTSBURG MINE.—Grass Valley Union, June 12: The water in the Pittsburg mine has been lowered to the 600 level, and a steam pump is now being put in which will drain the mine to the bottom, which is 900 feet. It will take several weeks to accomplish this, as there is a large extent of ground opened down to the 8th level. When all the water is out of the mine tribute contracts will be let to take out ore on the different levels down to the 7th, as there is yet plenty of ore in the stopes. No ground has ever been opened below the 8th level, although the shaft is down to the point where the 9th level is to be opened, and where the ledge is of good size and of fine milling quality. Preparations are also being made to introduce water-power for doing the pumping and hoisting, which will be completed within a month. The water will be brought in from the South Yuba canal, the supply ditch, reservoir and tank having already been constructed. A pressure of 200 feet will be obtained, and with a five-foot wheel all requisite power for pumping and hoisting will be had, as the left of water will be up to the 300 level, where it will be discharged through the drain tunnel. It is in further contemplation to introduce water-power to run the company's 10-stamp mill, but this will not be done until the lower levels are opened and yielding a regular supply of ore. The Pittsburg mine has a good history. It has yielded over \$1,000,000, and when underground work was

suspended several years ago a good ledge was showing at the bottom, but the machinery was not sufficiently strong to handle the water. In the meantime a long drain tunnel has been run to command the water to the depth of the 300 level, and this having been completed all arrangements are now being perfected to start up the mine again with an adequate force.

THE BADGER MINE.—The work of pumping out the Badger shaft goes steadily on. Thursday but very little progress was made in lowering the water, owing to the old cross-drifts and stopes being filled; but yesterday morning the water was brought below these drifts and the pump was gaining rapidly. The shaft is now clear of water to a depth of about 75 feet, and it is thought the whole shaft will be drained in a few more days.

Placer.

REPAIRING MILL.—Placer Republican, June 6: Since the Rising Sun and Big Oak Tree mines consolidated, the manager has been overhauling and repairing the old 20-stamp mill on the Rising Sun ground so thoroughly that it amounts almost to the building of a new mill. There will be new and improved concentrators and it is expected the mill will be at work in two weeks. In the meantime 20 miners are taking ore out of the Big Oak as fast as they can drift, no stopping being done at present, and a big dump is ready for crushing.

TUNNEL.—The tunnel of the Dam mine near Michigan Bluff is now in 4000 feet. Good pay has been found and the force of men has been increased. Eight of the ten shares of stock are held by Ed Polifka, one by C. F. Morgan, and one by Nathan Dinsmore.

IOWA HILL.—W. L. McKewen, U. S. deputy marshal, passed through town Friday, with several quartz miners, whom he intends putting to work on the old Poole ledge in Humboldt canyon. The tunnel at the McIntire mine, Giant Gap, is in 800 feet, and an incline runs 150 feet further. They have sunk their incline on the west rim of the channel with the bedrock pitching off at an angle of 45 degrees. They are running the incline east across the channel, the bedrock still pitching, and expect to break through into pay gravel at any moment. Mr. McIntire's perseverance and energy deserve success. The Watts brothers' drift mine at Monona Flat yielded 70 ounces of gold as the result of last week's work with three men. This mine is a regular bonanza to the popular Watts brothers.

IOWA HILL.—Argus, June 10: J. B. Hobson lately took a contract for running a 500-foot bedrock tunnel in the Morning Star mine. The prospects of that mine are very promising. Work was begun in the Sucker Flat mine by a small force of men under the superintendency of Mr. G. Hoffman.

Shasta.

QUARTZ AND PLACER.—Shasta Co. Democrat, June 9: F. B. Simonds, Sr., came down from Squaw creek yesterday and reports that camp booming. J. Vanoy is showing up a fine body of ore on the Newton, the claim adjoining the Uncle Sam, on Squaw creek. W. W. Nichols, of Copley, reports that Moore & Morton have "struck it rich" in their mine on Flat creek they recently purchased from an Indian for \$200. Three prospectors named L. E. Van Vliet, J. S. Shaffer and W. F. Doran, took out over \$1000 in the past two weeks, in a pocket ledge they discovered across from Middle creek station. Sunderhaus, Busch & Co. have commenced lively work on their mines they lately purchased on Squaw creek. They have shipped a large quantity of tools and provisions, and have put about 20 men to work already, at good wages.

DEADWOOD.—Cor. Shasta Courier, June 12: The largest coal-pit ever burnt in Deadwood, and probably in Trinity county, was completed last week by J. P. Hall & Co. It consists of 2000 bushels, the whole of which is for the use of the Brown Bear and McDonald Bros. mining companies. Belleau & Co. have a large force of men at work moving their mill and preparing for its reception on their new mill site. The contract for timbers for McDonald Brothers' new tunnel was let to-day to J. P. Hall & Co. It is to be six feet in the clear, and is expected to run from 1000 to 1500 feet. Everything about the timbering is to be substantial, nothing less than 8x8, from that up to 16. It may take a year or two to complete it.

Siskiyou.

SCOTT'S BAR.—Yreka Union, June 10: Bennett & Co. are about to start up operations in their claim back of Chinatown. J. Garretson & Co. are working in their hydraulic claim on Quartz hill. Their claim is continually sliding, which makes it easy pipping. Mr. McMurtry is talking of locating a quartz lead on top of Mt. Diablo, east of Scott's Bar.

QUARTZ ON KNOWNOTHING CREEK.—Numerous and remarkably rich discoveries in quartz continue to be made on Knownothing creek, a tributary of the South Fork of Salmon which comes in about four miles below Methodist creek. It is a comparatively new mining district, but it abounds with rich prospects and has a future as bright as New river or any of the new camps in the northern part of the State. Thomas Macaulay, an experienced quartz miner, writes to friends at Oro Fino that, in his opinion, the largest and richest ledges in the county are to be found among the recent discoveries upon Knownothing creek, and he has great faith in their future. The mines on Methodist creek continue to prospect richly, but we hear of no new discoveries.

Sierra.

PROSPECTING.—Sierra Tribune, June 11: Tuesday, Joe Perry and Dr. Hutchins left town before any but the very earliest birds were astir, on a prospecting trip. They were mounted on their own good legs, carried with them a pole pick and a com-misara in a tin pail. Crossing the river on a shaky log, opposite town, they struck out up the mountain. The hill is steep, and before they reached the top Joe asked the doctor how far it was to town. The doctor said he thought it was about 25 miles. They followed the river divide for several miles and came out on the South Fork, two miles above town. Several ledges were found and one location made. The snow is nearly all gone on the ridge, and they say there is a splendid country on that side of the river in which to prospect.

CHANGE OF SUPERINTENDENTS.—M. H. Mead has resigned the superintendency of the Young America mine. Mr. Mead was compelled to resign on account of other business demanding his

attention. Steve Moore, of Grass Valley, has been appointed to the position. Mr. Moore came up Wednesday evening. He is said to be one of the best miners on the coast. He was at one time superintendent of the Colombo mine of this district.

AT WORK.—Mt. Messenger, June 12: A. Vanslyke has several men at work on his quartz mine, near Butcher ranch, and will put on more men as soon as the snow gets off so that he can work to advantage. In a short time now he will have his engine at work, pumping the water out of the shaft. Jo Logarmisino is developing a very promising quartz ledge, situated upon the ridge between Butcher ranch and gold valley. He has a shaft down about 20 feet, and the ledge is four feet in width, of excellent quartz. He has some eight or ten men at work, sinking on the ledge and building a house. Wide Awake Company, Alabama Hill, have lately started a new tunnel, in now about 40 feet. Four feet per day is made, with one shift. It is expected to tap the pay lead about 300 feet ahead.

Trinity.

MINING MACHINERY.—Trinity Journal, June 11: Amos Melton and Henry Martin of the Brown Bear Mining Company, Deadwood district, were in town this week. At present the mill is shut down, as an additional battery of five stamps, new boiler and two more concentrators are being put in. Work in the mine is going forward and the usual quantity of quartz of regular richness is being taken out. The supply of rock is practically unlimited, as 15 men can easily supply all that can be crushed by the 15 stamps which will be in operation when the present additions are completed, in about three weeks from this date.

MOVING A MILL.—Messrs. Frank Balleau & Co. have purchased the Huntington mill and engine recently used on the Vermont mine by Pearson & Co., and are now moving it to the Belleau mine, Deadwood district. Good reports are anticipated from the latter mine when they get to crushing rock and taking out bullion.

HAY FORK QUARTZ.—A partial cleanup of the arastra on Hay Fork is said to have been very satisfactory to the parties interested.

NEVADA.

Washoe District.

HALE AND NORCROSS.—Virginia Enterprise, June 12: On the 2900 level the face of the north lateral drift is in a promising vein formation of quartz, porphyry and clay, but, as a small seepage of water comes in, the diamond drill has been started from the face and is driven straight ahead toward the Savage line, in order to feel for and guard against any possible strong influx of water from that direction, and also to measurably prospect the ground before advancing the drift further. On the 3200 level the lateral drift south, from the bottom of the deep winze, is out 94 feet, and has about 170 feet further to go in order to connect with the Combination shaft. Nothing further is to be done with the fine ore deposits found in the explorations above the 3100 level at present, or until the Combination shaft is sunk and connection made with it through the drift on the 3200 level. With the present heavy discount on silver, the ore is well enough where it is.

CHOLLAR.—The Chollar-Norcross-Savage or Combination shaft is now down 34 feet below the 3200 level, making a total of 234 feet in depth. The sump or drainage well portion of the shaft is now being sunk. About 50 feet will be required for this, making it, when completed, 50 feet below the 3200 level, or 3250 feet in perpendicular depth from the top to the bottom of the shaft. It is calculated that this 50-foot sump will be completed about next Wednesday, after which the station at the 3200 level will be opened for a drift north to connect with the drift now coming from the Hale and Norcross deep winze on that level. This station will be in reality eight feet below the 3200 level, in order to correspond with the grade of the Norcross drift. The bottom of the shaft is in excellent sinking ground, principally porphyry and clay, with considerable quartz and no increase of water. In fact, since the shaft entered the ore channel no water has been encountered worth speaking of.

SAVAGE.—On the 600 level the main lateral drift south is in 165 feet from the Gould and Curry south line, and has about 200 feet farther to go in order to reach and connect with the main Savage shaft. The material in its face is principally quartz of a very promising character, carrying spots of good ore. The crosscut east from this main drift is out 55 feet, and has cut into stringers of ore which assay well, and showing improvement as farther passed into.

CON. CALIFORNIA AND VIRGINIA.—The daily output of ore from the various producing sections is about 400 tons per day, the old stopes and breasts holding out well, but the quality of the ore does not hold out as well as the quantity, the assays from the mill battery samples averaging only about \$10 per ton. Active explorations are constantly carried forward at various eligible points with a view to finding something better, or more of the same.

GOULD AND CURRY.—The upraise incline is 63 feet above the 500 level, following the slope of the vein, 33 feet having been added during the week. The west crosscut from the upraise, on this level, was advanced 10 feet, making a total length of 79 feet. Material at both points principally quartz of very low grade.

SIERRA NEVADA.—On the 520 level the new lateral drift north from crosscut No. 2 has been extended 57 feet, making a total length of 78 feet. The lateral drift south at this same point was extended seven feet, making a total length of 29 feet. Both drifts are in very promising vein matter with no water.

BEST AND BELCHER.—The water in the Osbiston shaft has been lowered 11½ feet, leaving 16 feet farther to reduce in order to reach the track floor of the 2300 or bottom level, which corresponds with the 2500 level of the C. and C. shaft.

POTOSI.—Very little progress has been made in the diamond drill explorations to the eastward since last week's report. The proposed new drill hole, 75 feet farther south, mentioned last week, will be started to-morrow, preparations being now in progress to that effect.

YELLOW JACKET.—Daily yield 140 tons of low grade from the various old stopes and breasts from

the 1300 level up. Considerable dead work continues to be done in the way of explorations at various points for more ore.

CROWN POINT AND BELCHER.—Daily yield 375 tons. Some little improvement is reported in the quality of the ore between the 1750 and 1600 levels, otherwise the character of the general yield is about the same as heretofore.

MONTE CRISTO.—Work is still concentrated on running the drift west from the new shaft on the 150 level. The rock is hard, and advancement correspondingly slow.

OPHIR.—The main south drift on the 300 level has cut through into the old workings and is now running in a vein or deposit of low-grade ore.

KENTUCK.—The old workings continue their daily yield of about 60 tons of low-grade ore, taken from various points above the 1300 level.

ALTA.—Still drifting on the 700 level to connect with the old workings of the Lady Washington mine.

Bell District.

PROGRESSING.—Belmont Courier, June 9: Work is progressing steadily in one of the mines of Bell district.

Cherry Creek District.

LOOKING UP.—White Pine News, June 13: It has been a long time since we have heard of anything that gave us more pleasure than to learn, as we do by the following letter from our old friend, J. B. Williamson, that Cherry Creek is to revive this summer. The old camp has now lain dormant for more than three years, and the hope of the revival of at least some of its old-time prosperity will be welcome news to all our readers. Mr. Williamson says: I have just had a gentleman here to expert on the Exchequer property, and have bonded until the 1st of November the Exchequer group of mines, together with the mill, for a fine figure. The names of the parties are George T. Murdock, of New York, and Robert Chiboon, of Virginia City, Montana. They agree to put men to work on the 1st of July on mine and mill and make things lively for Cherry. Mr. M. Scramlin will take charge of the mill, put it in order and run it. Mr. Murdock will superintend the whole business himself as soon as he returns from California, where he has a gold-mining enterprise. Everybody here feels elated over the prospects for a little business. We have also bonded the Ruby Hill mines, belonging to B. B. Bird and myself, to B. F. Brooks, of Boston, and work has already been commenced on them under the management of R. A. McCormick.

Columbus District.

HOLMES.—Candelaria True Fissure, June 12: In the Murphy ledge we started a stope. This stope is up but a short distance. The ledge is three feet wide and the ore is good, assaying an average of \$60 per ton. This ledge looks very promising. It is situated in a portion of the mine that has never been prospected. In the main 10th we are still drifting east and from the crosscut toward the foot we are raising on a nice bunch of ore. The face of this drift does not show any ore, but it looks very favorable. The ground is hard and progress is slow. In the General Thomas or 11th level we have a good prospect. We are drifting east on a nice streak of ore. This is a good section, has never been prospected, and is east of all work done in this level. The ledge we are drifting on is near the foot-wall of the vein and it looks very encouraging. We are also running a drift from this level to cut the Price stope. The raise from this level is producing some good ore. The sulphuret winze is looking well and producing well. The ore from this ledge is high grade. The hot stope is looking well and has improved in size since last report. The rock around the ore is hard and progress is slow. It is a fine prospect and will give us a large amount of good ore. The stope 60 feet east of last turntable, first shaft level, has also improved very much since last report. We have a raise going up above the stope that is in good ore. The stope 50 feet below first shaft level, and directly under the last-mentioned ore body, looks well and produces well. Mill No. 1 is running half time on Mount Diablo ore. Mill No. 2 is running half time on Holmes ore.

Eureka District.

ORE SHIPMENTS.—Sentinel, June 12: During the past week ore shipments were made from the mines of the district to the two reduction works in town as follows: To the Richmond Works—Wood-chopper mine, 6 tons; Leonard, 1; Jones, 1; Atlas, 4; Iron Clad, 17; Mohawk, 5; Eureka tunnel, 1; Bullwhacker, 21; White Pine, 1½; Continental, 2; Antelope, 22. To the Eureka Co. Works—Dunderberg mine, 86 tons; Beck, 8; Bay State, 2.

Gold Mountain District.

PROSPECTS.—Candelaria True Fissure, June 12: R. Leisk, a large owner in the Hillside, Trowbridge and Independence mines, in what is known as the old camp, at Gold Mountain, returned from an inspection of his property last evening and left for San Francisco this morning. He brought with him 1000 pounds of ore which he intends having Professor Price experiment on. The ore is known to be rich and the ledges are quite extensive, and if the professor can successfully demonstrate the practicability of any process for the overcoming of its base constituents, Mr. Leisk and his partners will at once resume operations on the mines.

Hawthorne District.

THE NORTH STAR.—Walker Lake Bulletin, June 9: The improvements in the North Star Consolidated are making the managers and owners jubilant. Last week a series of assays were taken which gave an average of over \$125. This is not from a mere seam of ore but from several ledges of good width and extent, as shown by the present developments. A mill in Hawthorne district would be kept busy on ore from the North Star, and it is highly probable that one will soon be put there.

THE PARIGGI.—Tom Pesci is still driving a tunnel on the ledge of the Pariggi in North Canyon. The developments are very encouraging. The ledge is strong and averages \$65 in free gold.

Jefferson District.

CHLORIDERS.—Belmont Courier, June 9: Some good ore is being taken from the mines of Jefferson by the chloriders.

Jungo District.

LOOKING WELL.—Silver State, June 10: D. Le Barron was in town yesterday from Jungo district,

He reports the mines looking well in that camp. The miners McGill and Baldes, who were at work in the Silver Wing mine when J. P. Gensen was caved on and killed, were quite severely injured.

Northumberland District.

CHLORIDING.—Belmont *Courier*, June 9: Some chloriding is still being done in Northumberland district.

Ophir District.

MILL RUNNING.—Belmont *Courier*, June 9: The mill of the Chicago Mining and Reduction Company dropped stamps again on the first day of June. It is hoped that a long and prosperous run of this reducer of silver ores will gladden the hearts of the people of Ophir. The mine is looking well and there is an abundance of good ore in sight.

Palmetto District.

RESUMING WORK.—Candelaria *True Fissure*, June 12: R. B. Catherwood, one of the principal owners in the mining properties at Palmetto and Silver Peak, returned last Tuesday from making a thorough personal inspection of the mines and mill sites. He told a reporter that he was fully satisfied from what he saw that he and his associates would be justified in resuming operations. He at once telegraphed his report to New York and received advice in return authorizing him to go ahead at his discretion, and stating that money had been deposited to meet all demands. He has engaged men and purchased supplies, which will be forwarded at once and the work of cleaning out and repairing the shafts will be begun immediately and the mines put in thorough working order. This will, of course, involve a considerable outlay of money. Mr. Catherwood is pushing the preliminary work as rapidly as possible and will for the present make Candelaria the base of operations. He brought in some unselected samples with him that were taken from the bottom of a 70-foot shaft. They were assayed by the C. W. W. & M. Co. (Limited) and showed \$29 in gold and \$18.10 in silver. These samples were from what they call their low-grade ore body, and there are hundreds of tons of it in sight. In a mill-run from November 27, 1868, to January 20, 1869, the pulp assays went all the way from \$39.95 to \$201.51, but the appliances for saving the metals were so defective that a large percentage was wasted. That, taken in connection with the frightful cost of getting in supplies, necessitated the closing down of the properties. With the improved machinery in use at present and the great reductions in freight, Mr. Catherwood has not the least doubt of the entire future prosperity of Palmetto.

Pioche District.

A RESUMPTION OF WORK.—Pioche *Record*, June 5: The new company now forming, under the management of W. S. Godbe, for the purpose of working mines in Pioche, have titles to the property desired by them perfected. During the week negotiations for the purchase of all the right, title and interest to property owned by the Floral Springs Water Company, also the property owned by the Floral Mining Company, have been going on and consummated. According to a portion of an agreement recorded, all the above property has been turned over to W. S. Godbe, and \$2500 has been paid into the hands of R. H. Elam. The agreement between these parties has been placed in the hands of John Roeder, and when all its provisions are carried out, the money paid, a deed to the property will be given. What this agreement is we were unable to learn, as the parties appear desirous of not having it made public. Neither could we learn the stipend price, but believe it to be in the neighborhood of \$40,000. There are also negotiations going on for the purchase of mining property owned by C. H. Patchen and Mr. Shivers. Should the company succeed in purchasing these last mentioned properties, then this will give them nearly the whole of the north side of Spring mount. We learn that considerable of the stock has already been subscribed, and it is to be hoped that the company will soon commence active operations. Mr. Godbe made the remark that he was confident that he could work the black ledge ore.

Swanger District.

REORGANIZED.—Walker *Lake Bulletin*, June 9: A miners' meeting was held last Saturday near Hutton's Station, and Swanger mining district was reorganized. Some years ago this was a promising district and recently some valuable discoveries have been made which have caused a revival of interest in the old camp.

Tuecarora District.

NORTH BELLE ISLE.—Times-Review, June 11: The cross-cut near the shaft on the 150-foot level has been extended 16 feet.

NAVAJO.—The north drift on east vein from No. 5 cross-cut, 350-foot level, has been extended three feet, and work suspended for the present for want of better ventilation. South drift, east vein, 250-foot level, extended five feet. South drift from Johnson cross-cut, 150-foot level, extended 10 feet. No. 6 upraise on east vein, same level, has been carried up 17 feet. The stopes on 150-foot level are yielding their usual amount and grade of ore. Mill running on company and custom ore.

Tybo District.

STRIKE.—Belmont *Courier*, June 9: John A. Moore brought the news from Tybo that a rich strike had been made in the mine owned by Dimick, Luse & Turin. The ledge is large and carries ore that assays all the way from \$80 to \$200 per ton. Tybo will see a return of prosperous days should it prove anything like as extensive as the Two G.

Ward District.

LOOKING UP.—White Pine *News*, June 7: Ward is looking up. Between 30 and 40 men are now at work there, or waiting for the mill to start up. Czar Giddings has opened a boarding-house, W. R. Bassett the old corner saloon, and a celestial has gone over to open a restaurant. The mill will start up next week.

ARIZONA.

NOTES.—Prescott *Courier*, June 11: The Groom creek mill is crushing Parker gold rock. The Peck mill is ready for another long run. The Del Paso mill is making gold for its owners. Smith & Barnum are working their B. S. B. gold mine in Cherry creek district. It is four feet wide and pays \$20 per ton in free gold. They crush the rock by astrata.

KINGMAN SAMPLING WORKS.—Moberly *Miner*,

June 9: During the month of May these works report having purchased and shipped about 500 tons of ore, for which they have paid out to our miners very nearly \$50,000. This is the largest amount of ore ever run through these works in any one month, and the outlook for the continuance of the ore crop is so good that the proprietor, Mr. Foster S. Dennis, feels justified in purchasing new crushing machinery, for which purpose Mr. Cockburn went to San Francisco last week. When the new crushers are placed in position these works will be able to handle from 75 to 100 tons of ore every day in the week.

COLORADO.

POVERTY GULCH.—Elk *Mr. Pilot*, June 10: A rich strike is reported as having been made in the P. E. Islander a few days ago. An assay from the ore streak which is claimed to be 18 inches wide, by S. C. Robinson, gave 39 ozs. silver, 11 ozs. gold, and 70 per cent lead. The property is located on Cascade mountain, which lies at the mouth of Poverty Gulch, and is owned by Messrs. Brannigan and J. C. Quirrie, both of Crested Butte. We hope the assay shows the average value of the ore and that the pay ore holds its present stated size. We need a boom, and such a strike would give us a big boost in the right direction. James Welton, one of the Domingo mine lessees, was in Gunnison this week. He reports that he has probably 50 or 60 tons of ore on the dump for shipment and about 120 tons in the mine ready to take out as soon as more room can be had on the dump by removing that already out.

IRWIN.—The Bullion King is increasing its force of men. The Forest Queen is loading a car of ore this week for Gunnison, and has a hundred tons of concentrating ore on hand for the Metzger concentrator. The latter, formerly the Rose & Reed mill, is running regularly. Mat Nichols has returned and has charge of the mill. There are a number of promising claims here that might be leased, as the owners will not work them.

LEADVILLE.—Herald-Democrat, June 9: The La Plata smelter is still running only two furnaces. The ore receipts at the American smelter yesterday exceeded 300 tons. The shipment of ore to the Pueblo smelting works from this point is on the increase. The Mercury lease on the Delta is yielding fair gold-bearing ore. The Litter shaft, on Printer Boy Hill, has attained a depth of 450 feet. Mr. Maurice Starne, manager of the Litter property, on Printer Boy Hill, has returned after a short absence East. Mr. Perkins is meeting with gratifying success in the development of the Delta lode, on Printer Boy Hill. The property is producing some fine gold-bearing quartz, and also shows a fair streak of rich silver ore. Manager Kroger, of the Tip Top, after sinking the shaft through 20 feet of mineral, has cut a station, and is now engaged in driving drifts both north and west. The north drift shows ore assaying 35 ounces in silver to the ton, being quite an improvement on the mineral disclosed in the shaft. The north drift is still in sulphide ore, which will doubtless continue until the stopes made by the Forepaugh are reached. Good ore is known to exist there, and a profitable future for the Tip Top is assured beyond a doubt. The Chrysolite mine at present is doing very little. A considerable amount of exploration work is, however, in progress, and new resources may be opened at any time. At present the bulk of the first-class ore shipments are the result of the concentrating works of the company. These contain six jigs, which are kept running on material from the dumps about the Roberts shaft.

MONTANA.

TO START FOUR FURNACES.—Inter-Mountain, June 7: It is learned from reliable authority that to-morrow four furnaces of the Montana Copper Company will be started up under lease. The lessees will have sole management of the works and have contracted to run them principally on high-grade silver ore, which will be mixed with a proportion of copper ore from the Montana Company's mines, thus producing a copper silver matte assaying very high in silver. It is understood that a contract has been concluded with the company for the production of 300 tons of such matte. The run will be somewhat experimental in its nature, and is intended to demonstrate the advantages of working copper and silver ores together. The new enterprise is a most important one, and its result will be awaited with deep interest.

IDAHO.

SNAKE RIVER PLACERS.—Wood River *Times*, June 9: J. S. Hunt, owner of Hunt's placer claims, two and a half miles from Salmon Falls, is in town. He reports the outlook of the Snake river placers far better than it has ever been. In time, Mr. Hunt says, if artesian wells can be sunk in the lava between the railway and the river, millions of dollars' worth of gold will be washed out yearly. Mr. Hunt is operating three Burlap machines, or set of machines, on his claims. He uses from 150 to 200 inches of water per machine, and gets regular returns of \$350 to \$450 per machine per month. He has just added the third machine, and will soon put on a fourth and, possibly, a fifth. He does not believe in letting money stay in the ground, if it can be got out. While Mr. Hunt is satisfied with his yield, his ground is not near as rich as that of the Lucky Bar Placer Mining Company, whose location is about 20 miles from his. The machines at the latter place should yield much more than his, and the only question necessary to consider when trying to ascertain if the Lucky Bar operations will pay, is: Will the machinery raise as much water as it is claimed it will? If it does, or if it raises only half as much, the ground will pay handsomely. But even if it should not pay with machinery, the ground will pay enormously if free water can be got from Clover or some other creek which the company owns. It would, then, only be a question of the cost of putting in a ditch.

THERE'S MILLIONS IN IT.—Coeur d'Alene *Record*, June 9: Through the kindness of W. A. Parker, who has been superintending the work on the Badger claim which has just shut down for want of water, we can give a few facts of general interest. At a cost of about \$1850, some \$600 of which would have contributed to future operations if work had been kept up, gold to the value of \$7698.60 was taken out. This is a profit or net value of a full \$1000 per week.

A strip of 144 feet wide of the channel wash is stripped, and evidences are pretty clearly established that the entire width of the channel is about 250 feet. The depth to bedrock is now 35 feet. We frequently hear the theory advanced that this is an exceptionally rich claim, but Mr. Parker has made several tests and for nearly three years has studiously observed all the developments which have been made along this channel for a distance of nine miles, and he unhesitatingly expresses the opinion that it is not likely that there is a marked variation in the quantity of gold along the entire line. The width and depth of the channel will vary, and the distribution of gold will vary accordingly, and so will the cost of working. Mr. Parker is supported in this opinion by nearly if not every practical experienced miner who has taken pains to study the subject carefully. We have no doubt that as a mining proposition it is reasonably safe to invest money upon this actual knowledge and theoretical conclusions.

NEW MEXICO.

LEAD CARBONATE.—Silver City *Enterprise*, June 12: The Willis mine is shipping to this city for transportation to the Billing smelter at Socorro from three to four carloads of lead carbonate ore a week. Encouraging reports are daily received from the mine, and it is now almost certain that Gustave Billing will take it upon the expiration of his working bond. There is three feet of \$10,000 ore in sight in the Comstock, the great mine of Kingston. The lowest ore found will go over \$800 to the ton, and the average ore shipped goes over \$2600 to the ton. There is now 35 feet of an ore body in sight. Think of that, ye paupers, and gather up your blankets and play private secretary to a burro. Upon the completion of the Huson tramway on the Sheridan mine last week, C. W. Huson, the inventor, made a careful tour of inspection of the mining interests around Cooney, and to some purpose, as he purchased a one-half interest in three prospects, two of which make an excellent showing. They are known as the Oakland and Oakland No. 2, and were located by Eli Mader and Martin Johnson. Development on an extensive scale will shortly begin on a ledge that has already been prospected pretty thoroughly and shows 16 feet of pay ore on the surface.

SOCORRO NOTES.—Socorro *Bullion*, June 12: Wallace, Radcliff & Hadley will soon commence developing their Socorro City lode, situated in Water canyon. The Bonaparte mine, owned by Leddy & McLeish, is working and preparing to ship ore to Socorro for treatment. D. Langsdorf has purchased a half interest in the Quartzite from J. Kelly. It is situated in North canyon, Magdalena, and is showing up first rate. Shands and Leeson are spending the week at their St. Vincent mine, investigating the extent of their late strike of good-grade argentiferous galena. Jim Leeson, our enterprising merchant, is working four men on the St. Vincent, located in the north end of the Magdalenas, and is raising pay dirt. W. Hadley and J. Cowles have a fine-looking property located in the north end of the Magdalenas; the ore assays 47 per cent lead and from 5 to 15 ounces silver.

OREGON.

ALTHOUSE.—Cor. Rogue River *Courier*, June 11: Water drying up fast, and most of us miners are laying plans for the summer's work. Some of us are going to prospect for new fields of operations, the old ground being pretty well worked out. Hansen & Ehman are hard at work cleaning up, with favorable prospects for a good return for their winter's labor. James Turnhull has struck some good-paying gravel in his tunnel, after a year's bard driving through bedrock. Kline & Thompson are still working their old claim in the left-hand fork. Joseph Trimby has, I am told, sold out his claim to a China company for \$3000. All the miners on the upper waters of the creek are busy cleaning up, but I have not been advised as to the results. German, of Walker Gulch, has struck some new diggings on the upper waters, and is taking out some very pretty gold. Doyle & Crosby, of California Bar, Sucker Creek, have got their claim in first-rate condition for a long summer's work. The old man has just returned from a prospecting trip through Josephine and Canyon creeks. He found that there was some new ground being opened on the south fork of Canyon creek; also that there is some excitement about the mines on Chitico and its tributaries. Stewart & Co. are on one of the southern prongs, and have struck a fair prospect. They have built for themselves a cabin and got out lumber for sluices, and will be all ready to commence washing this week. John Hale, with a company of three others, will soon go over and commence operations at the same point. This gulch lies in the Coast Range, and about 24 miles southwesterly of Kerby. The trail runs up Canyon creek to Lightning gulch, and crosses the mountain down to the waters of Chitico. I was told that some coarse gold had been found in the Tin-Cup creek. This is another tributary of the Chitico river, but lies much farther west and is situated in a much rougher country.

UTAH.

PARK NOTES.—Park *Record*, June 12: The Marsac mill will ship to-day seven bars of bullion, containing 678.1 fine ounces of silver, as this week's output. The Mackintosh sampler received from the 5th to the 11th, inclusive, the following lots of ore: Ontario, 622,300 pounds; Daly, 236,280 pounds; and Woodside, 15,650 pounds. The Crescent shipped during the week 161,324 pounds of concentrates and 130,000 pounds of first-class ore. There is nothing new to report from the Apex. It is understood, however, that an increased force of miners will be put to work on the property soon. The Woodside mine is idle for the present. Negotiations to lease the property are now pending. A report to the effect that work is to be resumed on the Parleys Park on a large scale lacks satisfactory confirmation. Prospects at the Jupiter mine are bright. The mine is economically worked by a system of tunnels, and by the latter part of this month high-grade ore will be shipped in paying quantities to the sampler. The force now numbers six men and will be increased in about a month. Thursday was the Crescent Company's pay-day. The Southern Tier group of mines is being worked by seven men under the management of F. W. Hayt. Ore shipments will be resumed in about two weeks.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific States.

From the official report of U. S. Patents in Dewey & Co.'s Patent Office Library, 252 Market St., S. F.

FOR WEEK ENDING JUNE 8, 1886.

343,265.—EASY CHAIR AND SOFA BEDSTEAD—W. F. Bean, S. F.
343,220.—VERMIN EXTERMINATOR—F. E. Brown, Los Angeles, Cal.
343,434.—CAR COUPLING—J. C. Clay, Wells, Nevada.
343,364.—GRAIN SEPARATOR—B. D. Crocker, Walla Walla, W. T.
343,441.—ROTARY ENGINE—J. H. Darragh, S. F.
343,268.—ROCK CRUSHER—H. J. Dykes, S. F.
343,241.—WET ORE CONCENTRATOR—Jos. Hubert, S. F.
343,382.—GATE—W. Mason, Puyallup, W. T.
343,395.—PARLOR FIRE-PROOF SAFE—John Peterson, S. F.
343,283.—STOP-COCK—Wm. Swabel, S. F.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co., in the shortest time possible (by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Mining Share Market.

Mining stocks have not been at all active for the past week. The temporary closing down of two of the prominent Constock mines, on account of breakage of machinery, is the only event of importance from that section of country. The *Enterprise* states quite an improvement has been developed in the ore prospects of the Savage mine, on the 600 level, running south from the Gould and Curry, some very fine-looking streaks and bunches of good ore coming in. There is plenty of room for quite a bonanza to form at that point, and the management feel quite elated over the prospect. Other than this, there are no new features of interest to record in Constock ore development. The sinking of the Chollar-Norcross-Savage or Combination shaft makes excellent progress, being now in vein matter easily excavated. This shaft is now 3234 feet in perpendicular depth. The diamond drill operations on the 3100 of Potosi have made no decisive advancement worth mentioning during the week. A diamond drill hole is started from the face of the 2900 level lateral drift of Hale and Norcross toward Savage, in order to feel ahead as a precaution against any possible extra flow of water. The lateral drift south on the 3200 level from the deep winze is making good progress toward connection with the Combination shaft. The ore developments and indications on the 600 level are very encouraging and bid fair to lead to something important. The new work in Gould and Curry also promises well, and the low-grade bonanzas in Consolidated-California-Virginia and the Gold Hill section still continue their extensive regular yield in quantity, but at the north end the quality has rather deteriorated of late.

Bullion Shipments.

We quote shipments since our last, and shall be pleased to receive further reports:

Argus, June 10, \$17,860; Germania, 8, \$6377; Hanauer, 8, \$8575; Stormont, 8, \$2395; Queen of the Hills, 8, \$1100; Alice, 9, \$17,763; Hanauer, 9, \$2900; Germania, 10, \$1850; Hanauer, 10, \$5975; Pascoe, 10, \$1800; Queen of the Hills, 11, \$1200; Hanauer, 11, \$5980; Queen of the Hills, 12, \$1155; Germania, 13, \$5582; Hanauer, 13, \$8950; Queen of the Hills, 12, \$1300; Odessa mill, 12, \$13,600; Oldberg & Thede, \$13,300; Oro Grande mill, 12, \$8060; Monitor, 12, \$5000; Dexter, 12, \$18,400; Old Lexington, 12, \$3200. The Salt Lake metal and ore shipments for the week ending June 10th were as follows: 35 cars bullion, 858,498 pounds; 32 cars ore, 737,212 pounds; 5 cars copper ore, 150,300 pounds; — cars sulphur, 51,000 pounds; a total of 74 cars and 1,797,016 pounds. Wells, Fargo & Co. received \$78,450; McCormick & Co., \$73,875; I. R. Jones & Co., \$33,363; and Union National Bank, \$31,520.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

JARED C. HOAG—California.
J. J. BARTLE—San Joaquin Co.
G. W. INGALLS—Arizona.
E. L. RICHARDS—San Diego Co.
R. G. HUSTON—Idaho and Montana.
GEO. McDOWELL—Santa Clara and Santa Cruz Co's
J. B. PITCH, Nevada and Utah.
M. S. PRIME—Shasta Co.
FRANK W. SMITH—Oregon and Wash. Ter.
A. CALDERWOOD—Napa Co.

Complimentary Samples.

Persons receiving this paper marked are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber please show the paper to others.

Gardner Spring Governor.

TATUM & BOWEN,

25 to 31 MAIN STREET, SAN FRANCISCO, CAL.

91 to 93 FRONT STREET, PORTLAND, OR.

SOLE AGENTS FOR

GARDNER GOVERNOR COMPANY,

J. S. Mundy's Patent Friction Hoisting Engines.

The Mundy Patent has been sustained in the United States District Court of New York against the Ledgerwood Manufacturing Company, and also in the District Court in the State of New Jersey against Kendall & Roberts for infringement. Therefore all parties are cautioned against making, using, or selling Friction Drums that infringe this patent.

Gardner Governor.

GORDON & MAXWELL COMP'Y MINING PUMPS.

THE MOST EXTENSIVE PUMPING MACHINE WORKS IN THE UNITED STATES.

MORRIS COUNTY MACHINE and IRON CO. New High-Speed AIR COMPRESSOR.

We have recently furnished the contractors the machinery for La Trinidad (300 tons per day) and Silver Queen (100 tons per day). These mines are located in Mexico and belong to La Trinidad Company, of London. The Process is the Wet Concentration, and the Plants are, without doubt, the most substantial and complete of the kind ever built.

WE MANUFACTURE ENGINES, BOILERS, AND SAW-MILL MACHINERY, and Carry in Stock:

Wood and Iron Working Machinery, Best Belting, Lubricants for Cylinders and General Machinery Including the Celebrated ALBANY LUBRICATING COMPOUND.

1850. 1885.
RANKIN, BRAYTON & CO.,
...BUILDERS OF...
MINING MACHINERY.

San Francisco: 127 First Street. Chicago: 100 N. Clinton. New York: 145 Broadway.

PLANTS FOR GOLD AND SILVER MILLS, embracing machinery of LATEST DESIGN and MOST IMPROVED construction. We offer our customers the BEST RESULTS OF 35 YEARS' EXPERIENCE in this SPECIAL LINE of work, and are PREPARED to furnish from SAN FRANCISCO or CHICAGO, the MOST APPROVED character of MINING AND REDUCTION MACHINERY, adapted to all grades of ores and SUPERIOR to that of any other make, at the LOWEST POSSIBLE PRICES.

We are also prepared to CONSTRUCT and DELIVER in COMPLETE RUNNING ORDER, in any locality, MILLS, CONCENTRATION WORKS, WATER JACKET SMELTING FURNACES, HOISTING WORKS, PUMPING MACHINERY, ETC., ETC., of any DESIRED CAPACITY.

WATER JACKET SMELTING FURNACES

For COPPER and ARGENTIFEROUS LEAD ores of NEW and ORIGINAL DESIGNS, covered by LETTERS PATENT. No other Furnaces CAN COMPARE with these for DURABILITY, and in CAPACITY for uninterrupted work. MORE THAN 150 of them are now RUNNING in various parts of THIS COUNTRY, as well as many in FOREIGN COUNTRIES, giving results NEVER BEFORE ATTAINED as regards CONTINUOUS running, ECONOMY of fuel, AMOUNT and QUALITY of BULLION produced. These CLAIMS have been PROVEN BY RESULTS in ANY NUMBER of INSTANCES, and the GREAT SUPERIORITY of this SYSTEM of smelting ores DEMONSTRATED BEYOND QUESTION. COMPLETE PLANTS furnished to order of any CAPACITY, with ALL IMPROVEMENTS that experience has DEMONSTRATED as VALUABLE in this class of work.

Beyond question the cheapest and most effective machine of the kind now in use adapted to all grades and classes of ores.

This machine has been THOROUGHLY TESTED for the past TWO YEARS, under a GREAT VARIETY of CONDITIONS, giving most EXTRAORDINARY results. A recent COMPETITIVE TEST at the Carlisle Mine in Mexico, showed an ADVANTAGE OF OVER 30 PER CENT in favor of THE DUNCAN. The amount SAVED OVER THE TRUE being sufficient to PAY THE ENTIRE COST of the machines EVERY MONTH OF THE YEAR. One of its MOST VALUABLE features is an AMALGAMATOR. It saves all THE AMALGAM GOLD and SILVER that ESCAPES THE BATTERIES, PANS or SETTLERS, making the machine worth MORE than ITS COST for THIS PURPOSE ALONE.

Baker's Mining Horse Power.

Possessing all the requirements of a first-class hoist and affording means for the continuous operation of a Pump or Blower, without interfering with a hoisting apparatus. It is made entirely of iron, no piece weighs over 300 pounds. At the ordinary speed of a horse, a 1,000-pound bucket of ore may be raised 120 feet per minute. The hoisting-drum is under the complete control of the man of the shaft, and is capable of carrying 600 feet of five-eighths steel rope. SEND FOR CIRCULAR.

THE ROLLER ORE FEEDER

(Patented May 23, 1882.)

This is the best and cheapest Ore Feeder now in use. It has fewer parts, requires less power, is simpler in adjustment than any other. Feeds coarse ore or soft clay alike uniformly, under one or all the stamps in a battery as required.

In the Bunker Hill Mill it has run continuously for two years, never having been out of order or costing a dollar or repairs.

Golden State and Miners' Iron Works.
Sole Manufacturers,
237 First Street, San Francisco, Cal.

The Famous KNABE PIANO.

L. M. GOTSCHALK: "The best instrument now existing in both hemispheres."

JAMES LEFFEL'S Mining Turbine Water Wheel.

These Wheels are designed for all purposes where limited quantities of water and high heads are utilized, and are guaranteed to give more power with less water than any other wheel made. Being placed on horizontal shaft, the power is transmitted direct to shafting by belts, dispensing with gearing.
Estimates furnished on application for wheels specially built and adapted in capacity to suit any particular case.
Further information can be obtained of this form of construction, as well as the ordinary Vertical Turbines for Wooden Penstocks and in Iron Globe Cases, free of cost, by applying to the manufacturers,

THE FOOS MANUFACTURING CO., - - Springfield, Ohio

ADAMANTINE Shoes, Dies and Crusher Plates

ADAMANTINE.

We manufacture the above Adamantine Shoes, Dies and Crusher Plates. They are in use on the hardest quartz in the United States and South and Central America, and have been for the last ten years; we warrant them to outwear three (3) sets made of any other metal, and many report that they last from 4 to 8 times longer than any other make. They never break AT THE SHANK, and the wear is so light that little or no foreign matter gets mixed with the crushed ore.

Also CHROME CAST STEEL for Mining and General Use, of the finest quality.

For further particulars, address

CHROME STEEL WORKS,

H. D. MORRIS, Agent, 22 Fremont St., San Francisco.

When ordering, a rough sketch, with full dimensions, is all that is necessary.

CHILLED CAR WHEELS.

CALIFORNIA

ARTIFICIAL STONE PAVING CO.

(SCHILLINGER'S PATENT.)

—FOR—

SIDEWALKS, GARDEN WALKS, CORRIDORS, OFFICES, CARRIAGE DRIVES, STABLES and CELLAR FLOORS, KITCHENS, Etc.

The Courts here and in the East have decided that Artificial Stone Pavements with plastic concrete and in detached blocks, are infringements on the Schillinger Patent; and also, that when the plastic material is hocked off with a trowel and cut through far enough to control the cracking caused by shrinkage, that such pavement is in law the same as if laid in detached blocks, and is an infringement of the patent. All property-owners having such pavements laid without the license of the above Company, will be prosecuted.

PATENT LIFE-SAVING RESPIRATOR

Entirely Prevents Lead Poisoning
and Salivation

The most perfect appliance for people engaged in Smelting, Dry Crushing, Guano Works, Quicksilver Mines, Lead Corroding, Threshing and Stock-driving, and all other occupations where there is dust, poisonous vapor, or bad odor. In Feeding Threshing Machines, and similar work, they are indispensable, as no foreign substances can be inhaled when they are worn.

The Respirators are sold subject to approval after trial, and if not satisfactory the price will be refunded. Price, \$3.00 each or \$30.00 per dozen. Sent post-paid to any address on receipt of price.

HOOD'S FOUNDRY COKE.

Consumers are respectfully informed that owing to inferior brands of Coke having been sold in this and other countries under the name of "Patent Coke," the Glamorgan Coal Co. (Limited), Cardiff, in May, 1884, abandoned the title of "Patent Foundry Coke," substituting that of "Hood's Foundry Coke."

This Coke is exclusively used by the Selby Smelting and Lead Co., Union Iron Works, Professor Thomas Price, and other consumers here. Large quantities are regularly forwarded to Copper Smelters in Arizona and New Mexico, and also to consumers in Nevada and Salt Lake.

The undersigned are the SOLE IMPORTERS of the above Coke, which is for sale in quantities to suit purchasers.

\$1,000 CHALLENGE!

**THE FRUE ORE CONCENTRATOR,
OR VANNING MACHINE.**

PRICE: FIVE HUNDRED AND SEVENTY-FIVE DOLLARS.
(\$575 00), F. O. B.

OVER 1,000 ARE NOW IN USE. Saves from 40 to 100 per cent more than any other Concentrator. Concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order and ready to make tests at the Fulton Iron Works, No. 220 Fremont Street, San Francisco.

As the result of a suit East against an End-Shake Machine (the Embrey), similar to the Triumph, the Frue Vanning Machine Company owns the Embrey patent, and can put in the market an End-Shake Machine of earlier patent that will do as good work as the Triumph, and superior in construction and durability. There will be no risk of suit for infringement.

The Frue Vanning Machine Company warn the public that they claim and will prove the Triumph machine to be an infringement on patents owned by them.

Protected by patents May 4, 1869, Dec. 22 1874, Sept. 2, 1879, April 27, 1880, March 22, 1881, Feb. 20, 1883, Sept. 18, 1883. Patents applied for.

N. B.—We are and have been ready at any time to make a competitive trial against the Triumph, or any other concentrator for stakes of \$1,000.

Room 7—No. 109 California Street,

SAN FRANCISCO, CAL.

\$1,000 CHALLENGE ACCEPTED, PRICE, FIVE HUNDRED AND FIFTY DOLLARS (\$550.00).

**THE
"TRIUMPH" ORE CONCENTRATOR.**

The present improved form of the celebrated "TRIUMPH" Ore Concentrator possesses many advantages over any other style of Vanners, Vanning Machines, or Concentrators, yet introduced to the notice of mining men. These advantages consist in the superior features which enter into their construction, and facilitate their operation.

They are constructed in the best manner; their frames being of iron, insures their solidity, durability, and perfect steadiness of motion when operated. They are built as compactly as their requisite strength will permit, weigh less, require less freight space in boxes, by which their cost of transportation is reduced, and occupy less mill room when set up.

An important improvement has recently been introduced into their construction, which consists of a RIFFLE TABLE, placed in front of and which takes the discharge from the feed and amalgam bowl. The improvement is in the reciprocal motion which is imparted to this table by the longitudinal motion of the shaking frame to which the table is attached. We have at hand many testimonials, from well-known Superintendents of mines in different mining districts of the United States, bearing evidence of the efficiency and superiority of this form of Concentrator, and we shall be pleased to send Circulars covering such letters of testimony, and, as well, directions for setting up and operating these machines, and are ready to quote special prices for any considerable order.

IMPROVED FORM OF HYDRAULIC GIANTS.

The above cut illustrates the **IMPROVED FORM OF HYDRAULIC GIANTS**, which we manufacture. All similar styles are infringements upon this form, and a judgment stands of record to that effect, under the decision of Judge Sawyer of the U. S. Circuit Court in the matter of Hendy and Fisher vs. R. Hoskin et als.

Patents furnished upon application to

JOSHUA HENDY MACHINE WORKS,
39 to 51 Fremont St., San Francisco, Cal.

This cut represents our

**IMPROVED
HYDRAULIC
MACHINE.**

IT DIFFERS FROM THE OLD STYLE IN HAVING ONLY ONE JOINT instead of two. It is of greater capacity and more easily worked and kept in repair. The statement of Mr. Hendy that all styles are infringements on the machines made by him, he knows to be utterly false. All litigation has been in reference to old style two jointed machines, which are superseded by our new style one jointed. The decision of Judge Sawyer, referred to by him, is carried up on appeal to U. S. Supreme Court, with absolute certainty of a reversal in our favor. Send for Circulars and Price List.

VOLUME LII.
Number 26.

New Emery-wheel and Tooth Grinders.

We illustrate on this page two new tool grinders built by the Springfield Glue and Emery-wheel Co., of Springfield, Mass. Large emery-wheels, made especially water-proof, are used and arranged for grinding on the front side of the wheel, or on both the front and back sides, thus enabling front or back grinding, as may be desired. The machines take up little

minute of harder and sharper cutting grit. A machinist averages perhaps half an hour daily at a grindstone, and in a shop of 20 men 10 hours per day are consumed sharpening tools, which at 20 cents per hour amounts to about \$600 per year. This emery-wheel tool grinder, it is claimed, will do the same work in less than half the time, at a saving of over \$300 per year—more than enough to pay for the machine the first year, even if the grindstones cost

wheel is controlled by a valve to the desired amount. Four sizes of each style are manufactured, each using steel spindles from 1½ to 2½ inches in diameter, with frame proportioned to the size of emery-wheel used, as follows: 30x4 inches, 26x4 inches, 20x3 inches and 14x 2½ inches.

The same firm making these tools also manufacture a new automatic knife grinding machine, which is something superior to the

Gravel Mills.

Cement gravel, if rich enough, and sometimes gravel which is quite loose, is crushed in stamp mills of the same character as those used for quartz, but fitted with very coarse screens. In one water-power 20-stamp mill in this State crushing this gravel the stamps weigh 450 pounds each, and drop 90 times per minute with an 8-inch fall. Thirty miner's inches of

NEW EMERY-WHEEL TOOL GRINDERS OF THE SPRINGFIELD GLUE AND EMERY-WHEEL COMPANY.

room and are claimed to make less dirt than ordinary grindstones, and the workmen stand nearer the wheel, enabling them to more closely watch the work. The grade or coarseness of grit and any degree of hardness can be regulated and adapted to the kind of work to be done. The emery-wheel is made of emery and corundum, crushed down from large pieces by improved machinery to give each grain the most possible cutting corners. The particles composing the emery-wheel are sharp cut, and, being five or six times harder than those of an ordinary grindstone, are claimed to do so much more work. Thus a grindstone three feet in diameter, making 70 revolutions, gives 660 feet per minute of grinding surface, while an emery-wheel two feet in diameter can safely make 550 revolutions, and thus give 3460 feet, or over five times the grinding surface per

nothing. The emery-wheel in this machine is surrounded by a hood, except where the grinding is done, which prevents the water flying off, even at high speed, and is adjustable to the wheel as it wears away. The front section is provided with a pocket, with holes through it, to distribute the water over the face of the wheel as it leaves the pipe. This pocket being open, is easily cleaned of any dust or rust that gathers in the holes. An iron tank is placed under the wheel to receive the water coming from it, and to catch the waste ground off. The latter settles to the bottom out of the way, and can be easily carried away from time to time. This is an important feature. A second tank is placed by the side of this as an overflow tank, to which a centrifugal pump is connected by a pipe. The water is comparatively clean and is used over and over. The flow on the

general run of such machines. They are also makers of a fine grade of emery-wheels. Both machines and emery-wheels are carried in stock by the Stearns Manufacturing Company in this city, their Pacific Coast agents.

The big dredge working on the Potomac flats, near Washington, the machinery for which was built in this city on the same pattern as the Von Schmidt dredge at work on Oakland harbor, was burned last week, and seven men lost their lives.

A deposit of blood agate resembling Scotch blood stone has recently been discovered on Grand river, near Cisco, Utah. It covers a territory three miles square. The stones are large enough to saw into slabs for mantels and table-tops.

water, under a head of 130 feet, furnish the motive power. Of the total amount of gold saved, 80 per cent is caught in the battery. Outside of the mortar the pulp flows over silvered plates and thence through 800 feet of sluices.

In another mill in this State there are 10 stamps of 850 pounds each, dropping 90 times per minute with a 10-inch fall. There the coarser gravel and howlders are not crushed, but only the finer and softer gravel. The screens are sheet iron with 3-16th inch round holes. From 60 to 70 per cent of the gold sand is caught in the battery, with 20 to 25 per cent on the aprons. In a seven-months' continuous run the following results were achieved: Carloads of gravel crushed, 4241; total yield, \$44,835; average yield per carload, \$10.57; average yield per ton, \$7.05; average cost per carload of mining and milling, \$3.94.

The Vekol.

A Rich Mine and Model Camp.

Who has not heard of this now famous Vekol mine, and the fortune it has brought to its deservingly and enterprising owners? The Silver King has enjoyed for many years the reputation which its name signifies, and it has fully merited the designation. But even kings are supposed to be but the gifts of their mothers, and more remotely of their grandmothers. Without detracting a single silver thread from the crowning glory of the King, both in name and in its intrinsic value, the Vekol is the grandmother mine. The word is the Papago expression for grandmother, and the mine takes its name from the Indian trail of that name, which passes through the saddle-like pass of the mountain of the Bitter Well range, in which the mine is located. The hither well is in the Vekol basin, a natural opening about two miles wide by four or five miles long, surrounded on all sides by hills. The well is in its center, and was excavated earlier than Papago traditional history treats. No one knows its origin. It was in existence as long as the oldest of the present generation of Indians can remember. It is about 30 feet deep, the last 10 feet being through rock. Its top is about 50 feet wide and a path leads down its sides to the bottom. The water was quite brackish, and, since other wells were sunk into the basin, it has all disappeared. The other wells have pure and clear water, with the exception of one—a salt well, showing by analysis 500 grains of chloride of sodium to each gallon of water. The water is invariably found at a depth of 30 feet, below which no water supply has been found. Attempts have been made, and tubes sunk from 30 to 90 feet below the present water level have revealed no indications of water. The wells from which the water is pumped to the mine and mill are about a mile and a half to the northeast of the mine, in Vekol basin, and are nearly 500 feet below the level of the mill. Attempts were made to find water at a still lower altitude, and three wells were sunk at depths of 135, 218 and 160 feet respectively, but no water was found. The pitch of the stratification where water was looked for was followed without success. This water supply is not large, and only yields enough to keep the mill running six days in the week. Other wells are being dug with hope of securing more water.

The Mine.

The Vekol mine was discovered in January, 1880, and was located the following month. It was originally found by an old Papago Indian who had been working at farming with Mr. J. D. Walker. Another Indian had, fully five years previously, shown Mr. Walker from a distance where the mine was, but it was considered of little value and no attention was given to it. The second Papago brought some of the ore and was told that it was valuable and that he had better locate it. Several days afterward he returned and wanted Mr. Walker to locate it with him, as he was afraid the other Indians might cheat him. Mr. Walker made out the location notice from the description given and sent it out by the Papago to put up, and he followed a few days later, accompanied by Mr. Merritt. They dug on the ore and during the first day they took out everything in sight, about 200 pounds, which netted \$59. It really looked as though the ore was all taken out, but Mr. Walker thought he would further prospect it, and four or five months later he took a couple of Mexicans with him and succeeded in finding a little ore here and there until enough was secured to make a shipment to San Francisco, which brought back a return of \$130 to the ton. Since that time the work has been kept up almost continuously, the first-class ore being shipped and upon which about \$250,000 was realized, and the second grade ore was piled up on the dump until the 10-stamp mill was started up 10 months ago, since which time it has been constantly in operation.

Curious Features.

The formation is limestone and talc, in which the ore seems to be threaded rather than in a regular vein. It is not continuous for any great length, but is broken with the formation. It was found on an exposed face of the rock from which the barren croppings had apparently at some remote period broken away, and for a distance of nearly 500 feet up the face of the hill the gangue can be traced to the croppings which hide the treasure from all other view. The ore bodies generally run north and south. The ore is in bunches or pockets, sometimes several feet wide and again nothing but a mere discolored thread or seam for an indefinite distance, suddenly enlarging again into a pocket. Some of these pinched-out seams continue for 20 or 30 feet before a new body of ore is encountered, but one is sure to be found if the seam is followed. This irregular diffusion of the rich ore precludes the possibility of working the mine in that systematic manner which the thorough and experienced miners from the Comstock regard as the only proper way of mining. The ore seams radiate in irregular directions and the ore can be mined only by following them, or "coyoting," as the process is appropriately termed, and so long as this method produces the requisite hullion return and extracts all the pay ore to be found, it is perhaps as good a method as the regular plan, and in fact is the only system by which this peculiar mine can be

worked at a profit at all. There has been run in tunnels and shafts, in this way, from 5000 to 6000 feet in the aggregate, and from the nature of the works not a single stick of timber has been found necessary throughout the entire workings. Notwithstanding the apparent disadvantage of following such "streaks of rust," as one might call them, the rich quality of this ore amply repays for all dead work, and as compared with other producing mines gives results largely in favor of the Vekol, as will be seen from the following:

Statistics.

Between 550 and 600 tons of ore per month is milled. The ore is a chloride, much of which goes about 65 per cent in silver, and the mill works it up to 91 per cent of its assay value.

The lowest gross returns per month were \$17,000, and the highest about 25,000, and the total for 10 months was about \$218,000.

The cost of the ore, including every expense, such as salaries, insurance, repairs, milling, etc., is \$12.85 per ton. The milling alone costs about \$5 per ton.

The relative cost of the production of one dollar is 31 27-100 cents, leaving a profit upon each dollar produced of 68 73-100 cents. This is something marvelous, and yet the average profits during the current calendar are much better.

The proceeds of the mine in hullion, from July 1, 1885, to December 31, 1885, were as follows:

July	\$ 11,190 99
August	21,680 94
September	25,375 93
October	23,656 68
November	19,699 50
December	23,694 60
Ore shipped to Kansas City, being too refractory to be worked at their mill.	8,774 00

Total.....\$133,973 10

The number of tons of ore worked for the above time and taken out of the mine to produce the above hullion was 3371.

The total expense of producing this hullion, in six months, was \$41,904.40.

The hullion output for 1886 was as follows:

January	\$25,164 47
February	21,407 31
March	17,474 34
Total	\$64,046 12

Number of tons worked for above results, 1766.

Total expenses connected with the production of above hullion, \$22,756.70.

Relative cost of production, 23 13 100 cents; relative profits, 71 87-100.

Cost of mining, milling and all expenses, in 1885, \$12.85 per ton; in 1886, \$12.88.

The above figures are taken from the records of the company and are correct in every detail.

The company employs quite a number of Indian Papagos and Quajates for car and wheelbarrow men, and they are fully equal in these positions to any other race of men. One Indian in particular is a skillful and experienced miner. The payrolls contain about 60 men on account of the mill and mine, and these do not include any of those engaged in other or out-door work. The payroll aggregates \$4200 per month.

An Orderly Camp.

There is, perhaps, no other mining camp in the United States so quiet and orderly. There is not a saloon in the camp, and, therefore, no drunkenness. A saloon was started there some months ago, and during a little carousal some trouble was feared. The Messrs. Walker saw the necessity of prompt action and at once forbade their employees patronizing the saloon under pain of peremptory discharge from their service. The result was the saloon was moved away. The Indians and Mexicans are encouraged to save their wages and accumulate money. The company own the only store at the camp, but they advise their employees to purchase only such articles as they actually need. Any employee found guilty of theft or any grievous offense is at once dismissed, and by these means the camp is purged of all its elements of evil, and those who are really striving to do well are given the utmost encouragement.

Personal.

The mill and mine are under the direct superintendence of the Messrs. Walker Bros.—Judge J. D. and Lucien E.—and from personal observation and general report it is safe to say that good fortune never fell into better or more deserving hands. They are conducting their business upon an honorable basis with everybody.

Judge J. D. Walker is one of the pioneers of Arizona, and has resided here 24 years. His brother, Lucien E. Walker, has been a resident of Arizona for 10 years, engaged for most of that time in mining and prospecting.

Mr. W. T. Day is the general foreman of the mill and mine, and has been connected with the mine for two years. He is a faithful and competent man.

Mr. F. C. Minshall has charge of the mill and mill office and looks carefully after the interests of the company, and his services are highly appreciated by the company.

Mr. H. Hines is the assayer and refiner and he is pretty generally one of the busiest men connected with the camp. He is fully up to the standard in his profession and is careful and correct.

The general bookkeeper of the company is Mr. D. D. Denure, an accountant of skill and experience.—*Tucson Citizen*.

A Great California Quartz Mine.

Its Two Hundredth Monthly Dividend.

On Monday the Idaho Mining Company of this district, says the Grass Valley Union, declared their 200th monthly dividend. An event of this kind is deserving of more than a passing notice, as there is no history of anything like that number of dividends ever having been paid by a gold mine on the North American continent, and goes as a living proof of the reliability of gold quartz mining when intelligently and honestly conducted, and at the same time establishes the value and permanency of gold-bearing veins of the Grass Valley district, which have also stood high in the estimation of practical miners since the first discovery of gold-bearing quartz on Gold Hill, in the year 1850. Since then the working of quartz has been the principal feature of mining in Grass Valley, and has been the chief source of prosperity of the district. The Idaho mine is on the same lode with the Eureka, being the first extension east of that once famous mine, which yielded over \$5,000,000 before the rich pay chute dipped into the Idaho ground. The Idaho location (of 3100 feet) was made in 1863, but legal complications prevented any work being done until late in the fall of 1864, when a prospect shaft was sunk near the Eureka line, on the south side of Wolf creek. Work was afterwards suspended, and not renewed until some time in 1865, when John C. and Edward Coleman, who had previously been the principal owners in the North Star mine, purchased a large interest in the Idaho. Under the superintendence of Edward Coleman the shaft was sunk to the depth of about 300 feet, when a drift to the westward encountered the pay chute. Almost immediately the success of the mine was assured, and not long afterward a 15-stamp mill was erected on the ground, which was subsequently enlarged to 30, and at a later date to 50 stamps.

The yield of the mine partially paid for development work and improvements, and in January, 1869, the first dividend was declared, and in all that year there were seven dividends, and since that time (17½ years) with but few intermissions regular monthly dividends have been paid, the ones announced for the present month being No. 200. In that time this product has been something over \$8,000,000, and the dividends paid therefrom somewhat exceeding \$3,750,000, or over \$1200 per share on the 3100 shares of capital stock of the original par value of \$100 per share. During this period the mine has been opened down to the 16th level, which is 2200 on the incline and 1600 feet in perpendicular depth, and the shaft is now being sunk for the 17th level. A remarkable feature of the mine is that the lode has carried but one pay chute, hearing eastward, and all the levels of the mine below the No. 7 have been driven eastward, as all the pay has been in that direction. The pay chute has varied in width and value, some of the levels having been driven 1200 feet through pay ore; but the ore was not always of high grade, although seldom so poor as not to leave a margin of profit. The dip of the pay chute is toward the Maryland ground, which it will ultimately reach, as the lower workings of the Idaho are well advanced toward the Maryland line. During all the real working history of the Idaho, Edward Coleman has been president and superintendent of the mine, and John C. Coleman treasurer the greater portion of the time, and that the administration of the affairs of the company has been in every respect faithful the remarkable success accomplished is sufficient evidence.

THE MAD OX MINE.—The Mad Ox mine was located in the fall of 1859 by N. A. Peckham, an old but energetic miner. In the spring of 1860 he erected a two-stamp mill near the mine. The battery used was made of wood, roughly hewn from the trunk of a tree; the stamps were also made of wood, the shoes and dies alone being iron. Finding that this process would not work, Mr. Peckham built an arrastra, which worked very successfully for awhile, but being tired of this kind of labor he retired from mining in the year 1876 and sold his property to Grotesford, Strode & Co. Wm. Bickford, one of the company, sold his interest in the property to O. P. Woodward, in 1878. A wagon road was completed from John Harrison's vineyard to the mine in the year 1878, and a five-stamp mill was erected at the junction of Mad Ox and Whiskey creek for the purpose of crushing the ore taken from the mine. The mine was worked quite successfully for a time and yielded large dividends; its widespread reputation soon attracted the attention of mining men and experts from all parts of the State. In the year 1880 J. B. Haggis, of San Francisco, bought the property and erected steam power, also placing another five-stamp battery in the mill. Seeing that the mine was a good one, Mr. Haggis started a Barleigh drill to work and completed a tunnel 750 feet in length, thereby tapping the mine 637 feet below the surface. Many pounds of bullion was taken from the mine during this period. Work was suspended on the mine in the spring of 1885, A. H. Shnabel then being superintendent. The mine has since been idle until about two weeks ago. Louis Reel and James Duffy, two good miners, obtained a lease of the property. They have prospected the mine thoroughly and are satisfied of doing well in their new enterprise.—*Shasta Courier*.

The Prospector.

This superstitious belief is an old one, that unless the discoverer of a camp meets an untimely or bloody end, his find will never amount to anything; and this seems borne out by facts, since nearly all the discoverers of the great gold mines in the United States, with but few exceptions, have, as the saying goes, "died with their boots on." Of 38 booming towns in the early days, the locators of 12 were killed by bullets, three were buried in their creations by cavings, and the rest drifted away with the tides of immigration, have become lost in oblivion or died and were buried in paupers' graves.

George H. Fryer, from whom the celebrated "Fryer Hill," of Leadville, derives its name, died at Denver not long ago from an overdose of morphia administered by his own hand. Two years previous to his death he was worth a million or so; but he died a pauper and almost without a friend.

Old Virginny, after whom the "Consolidated Virginia" was named, and who sold his claim for \$25, a pony and a bottle of whiskey, came to his death by an overdose from a hucking mule near Dayton, Nevada.

Bill Bodie, the discoverer of the great Standard mine, in Mono county, California, slept his life away in a snow storm while making his way to the mines.

Col. Storey, who gave his name to the county in Nevada where the Comstock is situated, was killed by the Pyramid Lake Indians.

Thomas Page Comstock died a beggar in a straggled land. "Old Pancake," as he was known in the mining camps, committed suicide at Bozeman, Montana, on September 27, 1870, by shooting himself. He was the leader of the famous Big Horn expedition that was sent out by Nevada capitalists in search of the Lost Cabin mines, supposed to be somewhere among the Big Horn mountains. The expedition was a failure, and Comstock, whether from disappointment or some other cause, while camped near Bozeman, drove a pistol ball through his head and died instantly. He was buried there, and his grave is unmarked and unknown.

Near the wild spot which 12 years before the hidden treasure of Alder Gulch was first revealed to him, William Fairweather was laid down to rest. Like poor "Old Pancake," this erratic soul stranded on the shoals of dissipation, although each in his day had turned a key—the one silver, the other golden—which unlocked millions for others but nothing for themselves. William Farrell, who "struck" Meadow lake, died a victim to remorse in one of the leading hospitals of San Francisco, "haunted by the spirits of 1000 deluded pioneers and prospectors passing and repassing his dying bed."

The locator of the famous Homestake, in the Black Hills, is said to have afterward turned road agent. Times going hard with him, he attempted to stop a stage loaded and prepared for just such emergencies, and he was planted alongside the road by the tender-hearted express agent whom he had tried to rob and kill.

Homer, of Homer district, followed in the suicidal tracks of Comstock. After squandering a small fortune he shot his brains out on the streets of San Francisco.

Doughnut Bill, "Old Eureka" Kelse Austin, Lloyd Magruder, "Nine-Mile" Clark and George Hankinson, Henry Plummer and scores of others died violent deaths in one way or another, and reaped nothing from the rich finds each had made in his day.—*Montana Cor. St. Louis Globe-Democrat*.

SHASTA MINES.—Gold mining was once the leading industry of Shasta county, but it has gradually and almost ceased. During the past two years, however, much prospecting for quartz has been done and with the best of success. Many silver and gold mines have been opened up, new quartz mills erected and supplied with the most approved and expensive machinery. The principal districts lately developed are the Iron Mountain mine, 14 miles from Redding, where \$125,000 worth of machinery has been put in place the past season. In the Slate creek district, 35 miles north of Redding, \$100,000 has been invested in machinery. Numberless sales of claims have been made at high figures. Great activity prevails at French Gulch. Many new mills are being erected, and in the Old Diggings, eight miles north of Redding, a number of mills are paying well. At the Tellurium mine, near the town, a mill is in process of construction and will soon add largely to the wealth of the county. Rich iron and copper ores have been discovered in vast quantities. Marble, lime and sandstone are found in abundance. Coal has also been discovered.

CUSTOM SAMPLER.—Let our miners rejoice, for at last a scheme is on foot for the erection of a custom sampler in this city. It has been quietly worked up and will be owned entirely by Conway, Posey & Hewkins, Meredith & Ailman, John S. Swift and Dan'l Coomer. The motive power will be furnished by the Flagler works, but the machinery will be in a separate building and will not be otherwise connected with the Flagler concern. A side track will be run from the railroad alongside of the building, that ore by the carload may be handled at a slight expense. It is the intention of the promoters of the enterprise to buy ores. All of the preliminaries have been arranged and the new building will soon be in course of erection.—*Silver City Enterprise*.

The Hartsfeld Smelter.

Sixty Tons of Ore Smelted at Cœur d'Alene.

Through the courtesy of Alfred Brile, of the Kentucky Mining and Smelting Company, says the Cœur d'Alene Record, we received at a late hour this afternoon a report of the trial of the Hartsfeld smelter at Milo.

After repeated delays and discouragements the smelter was started at 8 A. M., May 26th, and tapped the first slag 30 minutes later. The ore ran from several different mines, the names of which it is not necessary to give. The furnace was started without lead in the lead well, and after a run of four hours seven bars of bullion, weighing 700 pounds, were drawn; a result equal to the highest expectation of those interested.

The average amount of ore run while the test was being made was 2500 pounds per hour. There is no question but that the furnace will smelt 30 tons per day, and do it easily. That is all that has been claimed for it at any time. With the necessary amount of flux, the slag when tapped run as freely as water. An average of 40 bushels of charcoal was used to every ton of ore, 2400 bushels in all being used. The charcoal was poor, it having been burned last February, since which time it has lain out exposed to the weather, without any covering whatever. After a run of two days, and when 60 tons of ore had been smelted, the smelter was shut down, the bottom of the furnace dropped, all thoroughly cleaned, the bottom replaced and everything put in readiness to run again in less than two hours. The condenser saves 10 per cent of the original weight of the ore, and there is no drawback whatever about the operation of any portion of the machinery.

Assayer's Report.

The following is the report of Longee & Co., who completed the assays to-day:

Bullion—64.41 ounces in silver.
Flue dust—6.08 ounces in silver.
Slag—Trace of silver and lead.

Ore Assays.

No. 1—13.37 ounces in silver and 55 per cent lead.

No. 2—9.72 ounces in silver and 37½ per cent lead.

No. 5—1.32 ounces in silver and .03 per cent lead.

Only one ton of the best ore mentioned (No. 1) was run, 50 tons being from Nos. 2 and 5.

The above figures speak for themselves and need no comment. The result of the test run banishes all doubt as to the success of the enterprise, and we heartily congratulate Mr. Brile and the company, for whose interests he has been such an able and untiring worker. All who are familiar with the progress of the work know that it has been pushed with energy in the face of many difficulties and discouragements. Its success means much for Cœur d'Alene and especially for Yreka district. Miners should do all they can to encourage, and nothing to discourage, the development that ought now to be rapidly made. All the gentlemen connected with the Kentucky Mining and Smelting Company merit a rich reward, and we heartily hope they will get it.

GOLD AND SILVER.—London advices state that the Royal Commission on the Depression of Trade has issued its third report, which concludes as follows: "Regarding trade transactions between gold using and silver-using countries, it is probable that inconveniences and serious losses have arisen from fluctuations in the relative value of the metals, especially when these changes are numerous and sudden. It is even possible they have tended in certain cases to divert the course of trade and to produce the depression from which this country is now suffering." The commissioners offer no direct opinion on this question themselves. They circulated a number of questions among gentlemen who from their practical experiences or researches into the subjects appeared likely to afford useful information. The answers received to these questions will, they think, afford material for the prosecution of further inquiry into the subject. The commissioners propose, in their final report, to draw attention to those portions of the evidence already given which bear upon the effects produced on our trade by the existing state of the metallic currency of the world. They are strongly of the opinion that the question deserves separate examination from other points of view than that of the commission, and apart from its general connection with the depression of trade. It should be treated with reference to England's currency system as a whole, and in relation not only to her commercial policy, but to her colonies, to India and to foreign countries. In conclusion, they say: "We humbly submit to your Majesty that from the general anxiety expressed on the subject, the necessity for such inquiry is urgent."

PROPOSED MINING TUNNEL.—On account of the heavy body of water in the Mayflower mine, the rich gravel drift claim at Forest Hill, Placer county, the pumping machinery is being taken out and preparations are being made to run a tunnel 5000 feet in length to strike the gravel channel at its lowest depth. Two shafts will be sunk on the line of the tunnel and five facers will be worked at once with the aid of compressors and power drills.

The Symes Mining Bill.

The changes in the Revised Statutes of the United States respecting the location and boundaries of mining claims as proposed in the bill recently introduced by Judge Symes have awakened considerable interest and caused lively discussions in the mining camps. The full text of the Symes bill is given below. While the proposed changes would undoubtedly check opportunities for litigation upon flat deposits and give original locators greater scope for securing the full benefit of their discoveries upon such deposits, they may, on the other hand, work detrimental to the interests of fissure vein claimants.

The bill amends Sections 2320 and 2322 of the Revised Statutes, and is as follows:

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled:

That Section 2320 of the Revised Statutes of the United States be, and the same is, hereby amended to read as follows:

"Section 2320. Mining claims upon veins or lodes of quartz, or any other kind of rock in place, bearing gold, silver, cinnabar, lead, tin, copper, or any other kind of valuable mineral deposits, hereafter located, may equal, but shall not exceed in area, 20 acres; but no location of a mining claim shall be made until the discovery of the vein or lode or other character of valuable mineral deposit within the limits of the claim located. Lode mining claims may be located in such form on the surface as the discoverers or locators thereof may desire, subject to the following limitations:

"That such claims must be substantially in the form of parallelograms where the boundaries of adjoining prior located claims or prior owned lands permit; and the length of such mining claims shall not be more than one-third greater than the width thereof."

Section 2. That Section 2322 of the Revised Statutes of the United States be, and the same is, hereby amended to read as follows:

"Section 2322. The locators of all lode mining claims or locations which shall hereafter be made on public mineral lands of the United States, their heirs and assigns, where no legal adverse claim or right exists at the date of discovery and location, so long as they comply with the laws of the United States and with the State or Territorial laws and local regulations not in conflict with the laws of the United States governing their pre-emption and possessory titles, shall have the exclusive right to the possession and enjoyment of all veins, lodes, and of all mineral deposits of every kind and character found or existing within the boundary lines of said lode mining claim extended downward vertically. Nothing herein contained shall be construed as giving any locators or owners of mining claims a right to follow any vein or mineral deposit outside of the vertical boundary lines of such claims."

Section 3. That all acts and parts of acts inconsistent herewith be, and the same are, hereby repealed.

THIRTY-SEVEN ENJOINED.—The Plumas National has the following: The last straw seems to have been added to our camel-load of trouble by the Superior Court of Sutter county. On the 25th of May last a complaint was filed in that court by the district attorney of that county, the county being named as plaintiff and 37 companies and persons engaged in mining on the tributaries of the north fork of Feather river as defendants. From the 8th to the 10th inst. the defendants were made recipients of peremptory writs of injunction issued on such complaint, and compelled to desist from mining. This proceeding was not unexpected. Some two months since our county was visited by one "Charcoal" Smith, an emissary from Sutter county. For the benefit of our readers we call attention to a few statements of the complaint. The wrong complained of is the prospective injury to the Sutter County Hospital and its grounds, valued at about \$3000. We learn that, prior to the days of hydraulic mining, the Feather ran in a well-defined channel, between natural banks sufficiently high to confine its waters and protect the land from overflow; that the deep holes in the river have been filled by tailings, thereby facilitating the downward flow; that defendants discharge during the mining season of each year 2,000,000 cubic yards of solid material into the river, 80 per cent of which eventually flows into the valley part of the main Feather; that it has so filled up the channel as during times of high flood to cause overflow and damage; that by reason thereof, plaintiff's said property has become greatly depreciated in value, and, unless defendants are enjoined, the said property of plaintiff will be utterly destroyed. The complaint is sworn to by one Metteer, a member of the Board of Supervisors.

The press of all the mining territories should lose no time in emphatically denouncing the Plumb bill now before Congress. A strenuous protest should be entered against its passage. It appears to have originated in a desire to prevent foreigners from obtaining great areas for cattle ranges, but it is said also to prevent them from purchasing or otherwise acquiring mining property. It will be seen at once that if it becomes a law it will be a serious blow to mining industries in many places. What we want is capital, foreign or domestic.

COMSTOCK ORE AND BULLION.—An abstract statement of the hullion product of the mines in Storey county for the quarter ending March 31, 1886, shows during that period 68,283½ tons of ore were extracted and crushed, the hullion product from which foots up \$816,464.96. The total cost of mining, transportation and converting it into hullion is given at \$834,879.64.

The Young America Mine.

The Sierra Tribune says: After going through the company's mill (as fine a mill as there is anywhere) we started up the trail to the mine. The distance by the bucket tramway, by which the ore is brought down from the mine, is 3200 feet, but we concluded before we got up that there must be some mistake about it. Arriving at the mine, we were taken in charge by Foreman Wm. Busch, provided with overalls, jackets and candles, and started in at the lower tunnel. We walked through tunnels and lateral drifts, climbed up slippery ore chutes, went through all sorts of narrow holes on all fours, and, after nearly two hours' hard work, emerged at the mouth of the first incline that was sunk on the vein. We do not pretend to be very well up in mining matters, but it was a curiosity to see the eyes of our companion, Dr. Hutchins, who is an old silver miner, stick out. There is good ore everywhere. There is hardly a place in the mine where the vein is less than four feet thick, and there are stopes now open where it is ten feet wide for long distances. The best of it is, it is all good ore, and there is a great deal of it very high grade. On the foot-wall there is a clay gauge of from four to six inches, and the hanging-wall is everywhere true and smooth. As the workings get deeper the vein stands more upright, making it easier to work. The ground is timbered in the most substantial manner, and every worked-out stope is carefully filled with "deads." All the drifts are laid with tracks of T rail, and cars are quickly loaded from chutes that are full of ore. This mine has now been working nearly two years, but a good beginning has hardly been made on the vast quantity of ore in sight. A tunnel has been started that will strike the vein several hundred feet below the present workings. We expected to see a good mine, but were not prepared for the great mine we saw. None of the present owners will live to see the Young America worked out. Superintendent Mead and Foreman Busch are "the right men in the right places."

THE BLOOD AGATE FIELDS.—Some eight miles from Cisco, on the Grand river, a large field of stone has been discovered, of a peculiar nature and of variegated and brilliant hues, which has puzzled mineralogists to classify, and which bids fair to add materially to the wealth products of the Territory. This stone, when cut and polished, resembles the beautiful Scotch bloodstone, now out of the market, and is capably adapted for all kinds of ornamental purposes and for jewelry. It lies on the surface ground, from the river back to the rising mesa, and covers a territory of some three square miles. In no other spot along the river or in the adjacent country has anything like it been found, nor in the country at large, except a small deposit, now exhausted, found in the State of Arkansas. Specimens have been exhibited in the city, and pronounced by jewelers as excellent for rings, pins, etc. The great value of the find lies in the enormous amount of the material, which is, in size, large enough to build mantels and other household adornments, and when placed upon the market it will doubtless meet a ready sale. A company is now incorporated to work this bonanza, and the gains will accrue to the benefit of several poor men, who originally found it.—Salt Lake Democrat.

STOCKHOLDERS ASK FOR A DIVISION.—Suit has been commenced in the Superior Court by A. C. Ellis and R. E. Doran against W. J. Sutherland, to recover \$59,290.66 on a contract to divide the proceeds of the reincorporation and sale of the Princess Mill and Mining Co., of New York, and the White Mountain Water Co., of Nevada. In the complaint it is alleged that the plaintiff executed an agreement with defendants in September, 1883, to equally share in the proceeds of the sale of the property of these companies, to the Candelaria Water Works and Milling Co., of England. The defendant was to pay them one-third of \$50,000 after the sale, which took place in London, and deliver to them 28,333 shares of Candelaria stock, the expense of completing a 30-stamp mill, however, to be deducted from the money. The contract was to be concluded before the 12th of last month. The terms of the contract, it is alleged, have not been complied with as far as the payment of the money and delivery of the stock is concerned, hence the suit.

GOLD IN COLOMBIA.—A Washington dispatch tells about an American expedition to the United States of Colombia. The dispatch said S. P. Bell furnished part of the money to equip the expedition. Bell said, yesterday: "There is plenty of gold down there. The climate is not unhealthy. The trouble is chiefly dealing with the inhabitants. They smile in your face and stab you in the back. They put off everything until to-morrow so often that an American loses patience. There is no way of getting machinery and supplies to the mines except on the backs of mules and Indians. It is tantalizing to think of the gold there that is just beyond the tips of your fingers. To get at it one would need to take 1000 well-armed men with ample supplies, and they would have to be familiar with the Spanish language and Indian lingo to make any headway. Such an expedition, if well disciplined, could bring back a shipload of gold; but anything less imposing is sure to get stranded in Carthage."

Strength of Timber in Building.

It is a fact well known to architects that the more kinds of materials we put into a structure the more we multiply differences of expansion and contraction, and in some cases that we have had our attention called to, the structure has been found sadly out of line, and its general appearance deteriorated by the difference in contractility of materials, and even kinds of one material, of which composed. Suppose, for instance, we construct a building 11 stories high, the walls of brick, wooden girders and partitions; we place joists across; these are green; we have 11 floors laid upon this green timber. The studding for each story is placed upon a firm foundation in the basement, directly over the top of which the partition timbers of the adjacent story are put, followed by another and another until the roof or rafters are reached, when the timbers or studding for the last story are the principal and often the only support. If we allow the usual per cent for shrinkage by seasoning, it is unreasonable to suppose that, with this 11 feet in width, the joists will so shrink that the roof will, by its own gravity, fall nearly one foot? Then, is it not equally pertinent to conclude that the base of the rafters resting on opposite walls alone will tend to crowd out until the apex finds solidity on these studs of the center, and thereby rendered unsightly, and possibly unsafe?

If mill-owners and operators, in filling orders for large stuff, would see that their timbers were gotten out so as to lie on edge when in position, and architects see that they were placed in position, as ordered, the shrinkage would only tend to make the joists stronger and the floors more solid. These are little things of themselves, but in the aggregate assume great importance, and more especially to those who pay the little bills or suffer the inconvenience of occupying buildings all askew.—California Architect.

MASTODON REMAINS.—C. W. Remsburg informs us that a discovery was made a few days ago on the ranch of his uncle, William Hazleton, that must be interesting to scientists. Mr. Hazleton lives in the edge of the foothills, five miles northeast of Centerville, on Kings river. Numerous bones were seen protruding from the bank of a small stream running through his ranch, and an investigation was made. The bones were about 10 feet from the surface of the ground. Among the remains were a number of large teeth, weighing about seven pounds each. Several very large bones, which fell to pieces and crumbled away immediately upon being exposed to the air, were unearthed. Among other relics were two enormous tusks, evidently having belonged to two different animals. The large one is over four feet in length and eight inches in diameter at the base. The other, which is considerably smaller and shorter, lay in such a position as to suggest that these leviathans may have come to their death in mortal combat. This locality has not been thoroughly examined, but the find must be of great interest to students of the ancient biology of this territory.—Fresno Expositor.

THE SAVAGE LEANING TOWER.—The tall brick chimney at the Savage hoisting works, if it doesn't tumble over, bids fair to become as celebrated an architectural curiosity as the famous leaning tower at Pisa, in Tuscany. The base of the chimney on the south has settled until the top leans two feet from the perpendicular. This can easily be distinguished by viewing it in a line with awning posts on the west line of C street. Notwithstanding the settling of the structure the masonry shows no sign of fracture.—Virginia Chronicle.

A SILK FACTORY PROJECTED.—It is said that the Visitation Manufacturing and Improvement Company will fit up within the next two weeks an old establishment in the neighborhood of the Six-mile House, on the San Bruno road, for the purpose of starting a factory for the manufacture of silk goods. The experiment was tried some eight years ago at the same place, but was given up. The establishment will be the only one of the kind on the coast.

VANITY.—Some one has said that every Englishman is an island and every American a Declaration of Independence. The Frenchman is vain because he belongs to so great a country, and the Englishman boasts because so great a country belongs to him. A Scottish driver of pigs once avowed that he was in some respects a greater man than Wellington, because the Duke could not have driven 700 pigs from Edinburgh to London, as he had done, without losing a single head.

OUR COAL SUPPLY.—One-fifth of all the coal produced in the United States is taken from the mines of only four counties of a single State, of which locality Pittsburgh is the business center. Nearly one-third of all the coal there raised is converted into coke—a business in which \$13,000,000 is invested and which gives employment to an army of 6000 men.

A LARGE WOOD SHAVING.—The widest shaving ever made by a wood-working machine was recently placed on exhibition in a store in Winchendon, Mass. It was 42 inches wide, several feet long, and of uniform thickness.

TABLE OF CONTENTS.

EDITORIALS.—New Emery Wheel and Tool Grinder; Gravel Mills, 421. Passing Events; Close of Volume LII.; California Observatories; Pacific Coast Lighthouses; Foundry Notes, 424. Working Gold-Bearing Sulphurets; Sizes of Screens for Ore; Academy of Sciences; Movable Gauge for Miner's Inches; High Explosives in Guns, 425.

ILLUSTRATIONS.—New Emery Wheel Tool Grinders of the Springfield Glue and Emery Wheel Co., 421. Diagram Showing Trade Number of Quartz Screens, 425.

MECHANICAL PROGRESS.—A New Cupola for Iron Foundries; Testing Water-tight Compartments; Manganese in Steel; A Novel Fire Box; The Steel Wire Gun; Gun vs. Armor Plate; Soap to Clean Steel; Glass Hand-wheels; Testing Iron and Steel; Proportionate Weight of Shafts; A New Pipe Joint, 428.

SCIENTIFIC PROGRESS.—Influence of Electricity on Plant Roots; The Early Oceans—Red Hot and Highly Destructive Vapors; The Polarity of Tadpoles; Source of Electricity in a Rapid Change of Temperature; Magnetic Qualities of Iron; Movement of the Washington Monument; Ocean Mountains; Thickness of Clouds; Invisible Sun Rays, 426.

ENGINEERING NOTES.—Eads' Ship Railway; The Germ of the Cantilever Bridge; The Panama Canal Enterprise; The South, 427.

USEFUL INFORMATION.—Coal Oil Noisances; Cameo Cutting; An Improved Sewing Machine; Bonnets Made of Paper; Steam Bicycles; A New Float; Decline in the Price of Magnetism; How to Kill Cockroaches; To Destroy Sound Cleaning Bronze, 427.

GOOD HEALTH.—A Small Fruit Dissection; Removing Objects from the Eye; The Effect of Alcohol; Inflammation in Eggs; Clothing of the Skin; Ice in the Sick Room, 427.

MISCELLANEOUS.—The Yekol; A Great California Quartz Mine, The Prospector, 422. The Harlequin Suetter; The Symes Mining Bill; The Young American Miner; Strength of Timber in Building, 423. **MINING SUMMARY.**—From the various counties of California, Nevada, Arizona, Montana, Idaho, Utah, Colorado, Oregon, Washington, New Mexico, 428-29. **MINING STOCK MARKET.**—Sales at the San Francisco Stock Board, Notices of Meetings, Assessments, Dividends, and Bullion Shipments, 432.

Passing Events.

The great Combination shaft on the Comstock has reached the depth of 3250 feet, and sinking has been discontinued for the present. A lateral drift north will soon be run and we shall see what will be found at the great depth indicated.

The strike among the iron-workers in this city against one of the foundries is an event of great local importance, and both employers and workmen are confident that they will be able to carry their point.

Mines all over the country are now in full swing, and a good summer's work is anticipated in many directions. California gold mines are still in good demand and being sought for.

Oregon and Idaho are both looking up this year and are attracting more attention from miners than heretofore. The news from Cœur d'Alene is quite encouraging for both placer and quartz.

The MINING AND SCIENTIFIC PRESS closes a volume with this number, and will begin a new one with renewed vigor and every promise of successful improvement.

THOUGH there are more men at work in Taylor now than at any time past, business men complain that it is much duller than a year ago.

Close of Volume LII.

Volume LII of the MINING AND SCIENTIFIC PRESS closes with this number.

As the PRESS is the oldest mining paper published in the United States, it is but natural that it should have long since established itself as an authority on this subject, and its patronage and prestige should have increased. With this widening of the mining field which has taken place in the last decade its influence has also widened by reason of its larger number of readers and patrons. There are thousands of men now engaged in mining where there were formerly hundreds, and mining is conducted in these days on a much better basis than 10 years ago. The methods, operations, systems and processes have all undergone more or less change. These changes are recorded in the PRESS as they occur, with all necessary details which would prove of interest to the progressive class of readers it has.

Abundant space is given for the current mining news, and a carefully compiled and condensed summary of this is given each week. Every effort is made to obtain all available information on mining and metallurgy which will be useful in the every-day work of the mining community of the coast. The selected matter is chosen with judgment, derived from long experience in the work. Our numerous correspondents aid us materially in bringing fresh information to the attention of our readers. The important progress in mechanics and science is duly recorded, care being taken to eliminate all but the really practical matter as far as possible.

In the matter of illustrations it has been the endeavor of the editors to bring attention more particularly to mechanical appliances of mining and metallurgy, interesting geographical features, and various kinds of machinery, which would be of practical use to the industrial classes of this coast. New inventions of interest have been given, and the more prominent Pacific Coast patents have been described. The very full index on the last page of this number gives a good idea of the scope of the subjects embraced in the columns of the PRESS.

As recently stated in these columns, the hullion product of the coast is gradually, but surely, increasing, showing conclusively the stability of the mining interests. So important an industry must maintain a representative journal devoted to its interest. It is no more than should be expected that miners everywhere should lend their aid and support by subscription and correspondence, and second our efforts in improving the PRESS. Those who are already its readers should call the attention of others to its merits, and induce them to become subscribers. With increased patronage greater improvements can be made. We aim to constantly improve the paper in every way and make it worthy of the patronage it receives. As a new volume commences a suitable time to subscribe is offered, for indexed files of the PRESS form a valuable mining and metallurgical library for reference at any time.

California Observatories.

The great dome, 70 feet in diameter, of the Lick observatory is being made by the Union Iron Works in this city, and is expected to be in place by November. The mounting for the telescope is in course of construction and will be sent here before long. Professor Holden expects that the whole observatory will be ready for use by August of next year. The work is being pushed as rapidly as possible, though much remains to be done, the great object glass not yet having been forwarded.

The Chahot observatory at Oakland is now open to the public on application to the superintendent, Fred M. Campbell. The assistants, Messrs. Chas. Burkhalter and Chas. Hill, are in nightly attendance. They have set the transit instrument, and the clocks, etc., are now in good order, so that observations for correct time are now possible. Parties visit the observatory every clear night.

Professor Frank Soule, of the Department of Astronomy of the State University, announces that the Students' observatory at Berkeley, now completed, will be open to visitors as follows: On the first Monday in each month, to the members of the several faculties of the University and the officers thereof, with their families; on the second Monday, to the

members of the senior and junior classes of the University; on the third Monday, to the members of the sophomore and freshman classes; on the fourth Monday, to the public generally. All are cordially invited to come as above specified. At all other times the observatory will, of necessity, be closed to visitors, owing to the regular work of instruction.

Pacific Coast Lighthouses.

The engineers of the lighthouse service on this coast have had some rather different experiences than has been met with elsewhere in the matter of fogs. The lighthouses which were built after the first settlement of the coast were put on the high headlands, as has been the custom all over the world. It was found, however, that many were too high, and if placed nearer water would throw light under the fogs which prevail here in summer. Several had, therefore, to be rebuilt, notably those at Point Bonita, at the entrance of this harbor, and at Point Conception. All the later lights have, in consequence of this experience, been built nearer the sea level.

More lighthouses will shortly be built on this coast, appropriations having been recommended in Congressional committee as follows: For continuing the lighthouse northwest of Seal Rock Point, St. George, Cal., \$50,000, the entire cost to be \$450,000; for completing a first-order light and fog station at Destruction Island, W. T., \$45,000; for construction of a second-order light at Point Sur, near Monterey, \$50,000; for construction of a second-order light at San Luis Obispo, \$50,000.

A first-order lens is about eight feet in diameter and 13 feet in height. The burner in the lens has nothing remarkable about it. It has a wick about four inches in diameter only. It is seen, however, at a distance of 30 miles. This is wholly due to its position in the reflector and the ingenious and scientific arrangement of the perfect glass triangle. Above the light is a tank filled with lard oil; below it is a reservoir, and a pump raises the oil to the upper tank, where the heat of the light keeps it from thickening. The chief duty of the tender is to keep the light in order and the reservoir filled. Said an expert: "It is not the isolation of the lighthouse nor its altitude that makes the first-order light visible for so many miles. It is the remarkable reflector which the lantern contains."

The lens to be placed in the second-order lighthouse at San Luis Obispo will cost \$20,000 when that structure is erected. The light which nightly glitters on the Farallones is thrown from a highly-polished and brass-trimmed reflector which cost upward of \$25,000. The light at Point Bonita, a second-order light and comparatively small, cost from \$8000 to \$10,000. There are first-class lights, similar to that at the Farallones, at Cape Mendocino, Point Arena, Pigeon Point, Point Conception and Piedras Blancas; that is, they are similar as regards reflectors. First-order lights are placed at commanding points or headlands. Some glow steadily with an unfailing signal, seen far out at sea; some revolve and flash.

MEXICAN MINING CODE.—A very useful little work for those interested in Mexican mines has been issued by the El Paso Times, El Paso, Texas. It is the new mining code of the Mexican Republic, and comprises also the ordinance providing for the organization of commissions, and a tariff of regular fees and salaries. The book is neatly printed and is sold for \$2. The work is one which many miners have wanted, as it comprises everything relating to laws concerning mines in Mexico.

ONE day last week in the New Almaden quicksilver mine, while prospecting an abandoned drift which had not been worked for more than 20 years, some miners found the skeleton of a man with a bullet-hole through his skull. It is believed at Almaden that the remains are those of Gumesindo Luera, a miner who disappeared about 20 years ago.

THE Paradise Valley Mining Company are talking of building a tramway from the mine to the mill, a distance of five miles. It is proposed to set up an endless wire rope between the two points, and carry the ore in buckets suspended from the rope. The estimated cost of the tramway is about \$35,000.

Foundry Notes.

"The Iron-workers' Strike."

The principal topic of interest among the foundrymen and iron-workers of this city is the strike at the Union Iron Works. The trouble originated in the boiler-makers' shop of the works some weeks since, and these men went out. The other trade unions, after some hesitation, joined these, and the hacking of the Federated Iron Council caused the others to go out too. This issue involved is not one of wages, but of the employment of non-union men. The union men wanted certain so-called "scabs" discharged from the shipyard; the managers deny having any employed, as the men so called have an organization themselves called the Wood, Iron and Ship-builders' Union. Between 200 and 300 men have quit work, but the works are not closed down, there being some 250 or 300 men in the shops, comprising those who did not leave, and others who have been engaged since. The manager of the works, Mr. Dickie, says: "The severe competition in all iron manufactories in this State, and the constant curtailing of business owing to dull times and the presence of agents of Eastern manufacturers, have cut down business in this city most seriously; the actual and threatened troubles in the labor market here have added to our difficulties, so that with our best efforts and strictest economy there is not much profit left, and the directors of the Union Iron Works propose to reserve to themselves the right to employ such men as suit the demands and exigencies of their business, without consulting any man or any body of men."

"We will be able to fill the positions made vacant by the pattern-makers in time. It may take a month, or it may take longer. We will also secure all the men we need; possibly it will take six months. But we are prepared for that and have not gone into this business to make a week's fight, but are prepared to give them all the battle they will want. We have at present all the men in the boiler factory that we can accommodate, and time will show that the other departments will be equally well supplied. The company is just as firmly determined as ever to make a decided stand, and under no consideration will the demand of the unions be acceded to. The fact of the matter is, these men demand of us what we cannot grant. We cannot and will not give way to them."

"In regard to our having work enough on hand to keep us busy two years, with a full force of men, such may be the case; but even so, two years is a long time and there is nothing to prevent us sending a portion of the work even to Europe to have it completed, and rather than give in to these men such a course will be pursued."

"The boiler-makers, backed by the Federated Trades, have demanded that we discharge all men in our employ who are not members of a union belonging to the federation. On that proposition the position of the company is just this: That they will not discharge a single man at the dictation of any union or any association of men. We have no antagonism for the unions, and have never taken particular interest in the question as to whether men belonged to unions or not, as long as they did their work properly. We do not propose one set of men can come to us and tell us another set of men shall not work. That is a proposition upon which we are firm, and we might as well shut up the works at once if we cannot run them to suit ourselves."

The iron-workers' side is summed up by one of them as follows: "This whole question with us is simply a matter of unionism. We have nothing to complain of ourselves, but as members of a union which belongs to the federation, we must support a strike which is ordered by the council. Such a strike has been decided upon, and we have nothing to do but to go out or be expelled as scabs. We have decided that the claims of the boiler-makers are just, and therefore we willingly assist them."

Among other opinions advanced by workmen which are worthy of note was that of one who made the appended statement:

"We belong to a federation, the objects of which are to aid us every possible way and to protect our rights against those who would infringe them. The council of that federation, composed of the ablest men in the organization, after mature deliberation have decided that it is to the interest of the federation to uphold the boiler-makers in their strike. That is all there is to the question."

Working Gold-Bearing Sulphurets.

Concentration and Chlorination in Nevada County, Cal.—No. 7.

(Written for the Press by C. A. SCHENCK.)

After the addition of the precipitant the solution is well stirred with a wooden paddle, so that the sulphate of iron gets well mixed with the lixivium and all the gold is precipitated. To be sure in this latter respect an excess of the sulphate of iron must be present, which is tested in the following way: In the beginning of the leaching, when the gold solution flowing into the tub is strongest, from one to two pints of it are set aside in a glass, whereupon, after the addition of the iron salt and stirring with the wooden paddle, and having also waited a few minutes to give the gold time to settle, a sample is taken from the vat in another glass, to which is now added some of the strong solution set aside. Enough of the sulphate of iron has been used in the gold tub if a precipitate is produced in this test. To be certain that all the gold has been leached out of the mass of ore in the chlorination vat and transferred to the precipitating vat, a test is made by means of the iron sulphate.

The Precipitated Gold

Which is obtained in this part of the process is of a brown color and in a finely divided state, and must be first washed and dried before being melted. The washing is performed in the following manner: The brown precipitate is transferred to a porcelain dish of required size and boiled on a sand-bath with sulphuric acid; after the boiling and subsequent addition of water the mass is transferred to a filter, drained and washed with hot water. The drying of the washed precipitate is done in an iron pan; the dried gold is then melted in a black-lead crucible and run into bars.

The mass of ore in the chlorination vat, out of which the gold has been leached as described, still contains

The Chloride of Silver,

For which the leaching agent is hyposulphite of lime. But the leaching of the silver by the last-named solvent is not done in the same vat, though there is no valid reason for not doing it. The ore being deprived of its gold, and having been left to drain for about 24 hours, is shoveled into similar tubs, standing on a lower level, whereupon water is first run through the mass to wash out the remaining base metals soluble in it, and when this is done the leaching with the solution of the calcium hyposulphite begins. By means of a trough in front of the line of tubs the silver solution is conducted to the silver precipitating tubs. The outflow should be so regulated during the leaching that the solvent covering the surface of the ore remains at about the same level. The wash water is not utilized. The trough in front of the tubs is divided longitudinally into two partitions, through one of which the wash water runs to waste. As soon as the hypo follows, which is indicated by a sweet taste, showing that silver has been dissolved, the stream is turned into the other partition, from where it runs into the silver precipitating tubs, in which the silver is precipitated by a solution of calcium polysulphide. An excess of this precipitant is carefully avoided because this excess would subsequently be carried back into the silver leaching tubs with the solution of the calcium hyposulphite, precipitating there silver as a sulphide, which would be lost. For this reason it is safer to leave a little silver in the hyposulphite solution, which is not lost, while on the other side it furnishes sure evidence that no excess of the precipitant has been used. That such an undesirable excess is present is easily detected in the following manner: Take in a test tube some of the clear solution from which the sulphide of silver has settled, and add a little dilute acetate of lead. A precipitate of sulphide of lead will appear if a trace of the calcium polysulphide is present. More of the silver solution must be run into the tank if such an excess is found.

In the Reaction,

Which resulted in the precipitation of this sulphide, the calcium of the polysulphide has taken the place of the silver in the soluble hyposulphite of silver, the silver itself combining with sulphur, which combination being insoluble forms a precipitate. In the remaining solution the hyposulphite of lime is regenerated, whereupon it is conducted to a well, from which

it is raised to the distributing tank for subsequent leaching.

The precipitate, consisting mainly of sulphide of silver, is cleaned out of the precipitating tank and transferred to a cloth-filter, from which the solution drains off; after washing it with hot water, draining again, pressing and drying, it is roasted in a small reverberatory furnace. The roasted mass is then melted in black-lead crucibles with scrap iron, which takes up the remaining sulphur.

Academy of Sciences.

At the last meeting of the California Academy of Sciences a paper was read by Mrs. Mary K. Curran, entitled "A Botanical Excursion in Marin and Sonoma Counties." Mrs. Curran walked, by herself, from San Rafael up as far as the mouth of Russian river, from there to Duncan's Mills, and thence to Healdsburg, where she took the cars for home. During her trip she collected large numbers of botanical specimens.

Dr. H. W. Harkness made a report of his recent investigations of the water of Mono lake, particularly with reference to its forms of vegetable and animal life. The sudden reddening of a bottle of this water, which has for some years been standing in the academy, led to the discovery of a form of animal life which led to his trip to the Sierras this month. He found the flora and fauna of the lake waters to be great in variety and number. The ruby-red color was due to the presence of bacteria of a new species. Five or six other animal forms, some of them animal feeders, were found, as well as 14 varieties of plant life. Of these, the ephedra was dwelt upon most largely, the larvae of which are in shrimp form and much liked by the Indians, who find them very palatable. One could digest them readily enough when once divested of the idea of eating the larvae of the worm. These are the largest of the bacteria, without doubt, yet known.

President Holden, of the University, made an impromptu address upon the condition of affairs and progress of the work at the Lick observatory at Mount Hamilton, particularly with reference to the construction of the great dome and mounting of the telescope.

B. B. MINOR, a man well known from his connection with the mining developments of

this coast, died at Los Angeles on Monday last. His face has been a familiar one in most of the more prominent mining camps on the coast.

A DISCOVERY of tin ore is reported about 12 miles from Olympia, Washington Ter.

Movable Gauge for Miner's Inches.

One of the simplest forms for measuring water is described in a Government report upon the placers of Boise Basin, Idaho. In this particular case the box, made of one and a half-inch pine boards, is 48 inches wide, inside measurement, by 16-inch sides. Across the bottom, at the delivery end of the box, is nailed a one-inch cleat or strip, which serves the double purpose of holding the lower part of the gauge box in place and of raising the aperture above the bottom of the box. Six inches above the upper surface of the cleat is a wooden bar nailed across the box and parallel to the cleat beneath. The bar is three inches high and is roughly marked at intervals across the upper edge of the supply side by saw-notches, which may be numbered by pencil marks. The orifice is therefore six inches high, and when fully open is 48 inches wide.

If the water in the box rises to the top of the cross bar, the head is then three inches above the top of the surface, or six inches above its center. Each inch of width of the aperture delivers six miner's inches, or a total of 238 miner's inches for the cross section of the whole aperture. The quantity of water allowed to pass through the box is determined by a gauge-board split to the required width and inverted vertically behind the cross-bar and bottom cleat, which holds it in position. In using this box in a ditch any space outside of it is securely calked with clay. It is a convenient form of movable gauge, which may be modified to accord with any of the various accepted definitions of the miner's inch.

High Explosives in Guns.

For a number of years past experiments have been going on in the endeavor to fire dynamite from a gun with black powder as the propelling force. The matter has by many been deemed impossible. A new invention in this direction by Lieut. J. W. Graydon and J. G. de Styak, of this city, has been tried recently with reported success. General Howard, of the U. S. Army, who is in command of this division, became impressed with the assertion of Lieut. Graydon concerning the invention and ordered a board of officers to report to him the results of the experiments. He gave the use of a three-inch Parrott gun for the demonstration. The board consisted of Major Harkin, Lieut. Slaker and Lieut. Harris. The report will be sent to the War Department.

At 1 P. M., one day last week, the firing commenced and was continued until 3:30 P. M., and until the board were entirely satisfied of the safety in firing. Projectiles 20 pounds in weight, containing three and one-half pounds of dynamite, displaced about three tons of solid rock. The board will report favorably on the advisability of allowing Lieut. Graydon to use larger guns, so that some idea of the effect of firing large charges of dynamite may be given. During the trials recently a dozen shells were fired, and at a range long enough to allow the two reports to be distinctly segregated. A large quantity of rock was blasted out of a solid wall by the experiments, and on one occasion a fence which got in the way was torn up for several yards. The gun used was an old condemned piece, and permission will be asked of the authorities at Washington by General Howard for a better one for the next demonstration, which will be with ordnance of considerable caliber. It is desired to fire 90 pounds of dynamite from a 15-inch smooth-bore gun. This will be a severe test.

JOHN BUIOLI, a miner in the Mount Pleasant mine, was poisoned last week, strychnine having been put in his dinner bucket. Buioli had a contract to work the mine, and his refusal to employ some other parties is the supposed cause of the crime.

FIVE cents apiece is the bounty paid in Modoc county for rabbit scalps, and the little animals are being destroyed by the wholesale,

MECHANICAL PROGRESS.

A New Cupola for Iron-Founders.

German contemporaries notice a new form of cupola, introduced by Greiner & Erpf, and stated to have been successfully worked at several places. In the ordinary cupola a main source of waste of the heating power of the fuel is found in the fact that a large portion of the carbonic acid, formed by the combustion of the coke at the tuyeres, is reduced to carbonic oxide in passing through the incandescent coke above, and passes away in that form out at the top of the cupola. Greiner & Erpf, in their cupola, burn this carbonic oxide again to carbonic acid, in the higher portion of the cupola, in such a manner that the heat so produced is used in warming the charge in the cupola, and the gas passing away contains only carbonic acid and no carbonic oxide. The lower tuyeres, where the combustion of the coke takes place, are quite as usual and worked in the ordinary manner. Above these are three circles of smaller tuyeres, arranged spirally around the cupola. Each tuyere can be easily opened, regulated or closed by means of a stopper, and each one has a glass-covered peep-hole to observe the combustion in the cupola. Experience has shown that, when the cupola is at work, there is a point above the combustion zone of the coke at which, by blowing in air, the carbonic oxide will ignite and can be consumed without the coke in the charge being burnt. This point will vary with the nature of the coals, pressure of the blast at lower tuyeres, etc., but can easily be found by observation through the tuyeres of the upper circles at varying heights. Air is then blown in at the proper point, and at the tuyeres above this, the pressure being so regulated that observation through the peep-holes shows that a continuous and progressive combustion of the gas is taking place without the coke being ignited at any part. The working and regulation of this cupola are stated to give no difficulty, and to have yielded excellent results at several works. In a cupola of 80 centimeters diameter, erected at one establishment, a trial was made in which 100 tons of iron were worked at 12 different meltings. The coke used was 5.01 per cent on the iron charged, and this is stated to represent a saving of 33 per cent, as against work in the old cupola of the usual kind. At other places where the system has been introduced, the coke per cent on the iron is given as 4.14, 4, 5.732, 4.5, which figures would vary with the quality of coke used.

Testing Water-tight Compartments.

An English exchange says that, warned by the fate of the *Oregon*, the Russian Government has been inaugurating an exhaustive test of water-tight compartments, which it contemplates applying to all new vessels, and probably to older ones as well. The man-of-war selected was the corvette cruiser *Vilias*, which was finished last autumn, and is under sailing orders for the Pacific this month. Five weeks ago an intimation was conveyed to the dockyard authorities at Cronstadt that the water-tight compartments would be tested in succession, and orders were given to survey them afresh, and make good any defects that might be discovered. If the official report is to be believed, every effort was made to meet the wishes of the Admiralty, yet when the compartments were actually filled with water the fluid gushed through numerous apertures which had escaped the eye, and in some cases to an extent that would have been troublesome at sea after a serious accident. To secure perfection several of the compartments were filled two or three times, and it was only after a deal of door-adjusting and leak-stopping that the corvette was pronounced fit to proceed to sea. A final test was then applied in the presence of the higher Admiralty authorities, a number of the nine large water-tight compartments being filled at once without any leakage. Besides insuring the rectification of all defects in the water-tight compartments it is claimed in the report that the tests have proved of great service in training the crew; they have promoted confidence in the buoyancy of the vessel, and have led to several improvements of an important character. It has been suggested that in this year's naval maneuvers in the Baltic the tests should be continued by ordering so many of the water-tight compartments to be filled, in the event of a torpedo cutter approaching within hitting distance of a man-of-war; but the defects revealing themselves in the case of the *Vilias* have made the authorities apprehensive of ill-results, unless harbor tests are applied beforehand.

MANGANESE IN STEEL is second as an element only to carbon. It is the combining element which makes cast steel possible. It would be practically impossible to melt pig and scrap iron, or pig iron and ore, and pour it into an ingot which would roll, as without it there would be sufficient oxidation to disintegrate the parts, causing it to fly to pieces as soon as it was rolled or hammered. Manganese has a greater affinity—that is, tendency to combine, for oxygen than iron has; so, if manganese be added either at the beginning or when the steel is melted, it will combine with any oxygen present, leaving the steel solid and free from oxygen. It must be added in excess to be certain to thoroughly deoxidize the steel, hence all cast steel contains more or less manganese. The

free manganese which is left in the metal after its use as an oxidizing element has a hardening influence. It is found in percentages varying from a few hundredths to over one per cent. The former percentages are found in some crucible and open-hearth steel, while the latter are by no means uncommon, particularly in Bessemer steel. The manganese is added in the form of spiegeleisen or ferro-manganese, which are compounds of iron, manganese and carbon, with silicon and other elements containing manganese in percentages varying from 10 to over 80. Before the introduction of cast steel manganese played no important part in the composition of steel, as it appeared only in inappreciable quantities, except in a few cases where the pig iron puddled was made from a highly manganiferous ore.

A NOVEL FIRE BOX.—Mr. C. K. Villas, of Alstead, N. H., recently patented a reversible rotative fire-box, consisting of a spherical chamber or box provided with perforated covers. By rocking this fire-box to and fro by means of a crank, ashes and clinkers may be easily removed. The apertures in the covers may be so small that very little coal can escape with the ashes and the objectionable process of dumping is thus entirely avoided. In building a fire the box is nearly filled with coal, which is kindled at the top; the apparatus is then reversed, bringing the fire under the coal, and in the same way when the fire goes out with the box nearly full of coal the above operation may be repeated without special inconvenience. By whirling the box around rapidly the ashes may be completely removed and the fire extinguished when desired.

THE STEEL WIRE GUN.—The new experimental 9.2-inch steel wire gun has just been tried at the government proof huts, Woolwich arsenal, with satisfactory results. The War Department has issued orders for the construction of several more guns of the same description. The government pressure test for the gun was 65 tons to the square inch. This new weapon weighs 25 tons and is 33 feet long. The steel wire is coiled round the inner tube at the breech and nearly up to the trunnions, and consists of 78 layers. The wire is made in lengths of 2400 yards. It is flat, and is put on by a specially-designed machine at a pressure of about 40 tons to the square inch. The lengths are joined by being brazed and riveted together over a length of 15 inches. After the wire has been put on, a steel jacket is shrunk on over it.

GUN VS. ARMOR PLATE.—The latest victory in the long-drawn match between the gun and the armor plate has been scored in favor of armor. At Spezia a German chilled steel armor plate, five feet nine inches in thickness, weighing 100 tons, was fixed against the face of the cliff and hattered with chilled shot from the 100-ton gun. A thunderbolt weighing almost exactly a ton was hurled against the face of the plate by the explosion of 750 pounds of powder without producing more than a slight indentation and some trifling cracks. Three shots failed to make any serious impression on the plate, which has thus come off victor in the struggle. It would seem that no shot yet invented will go through six feet of chilled steel. —*Pall Mall Gazette*.

SOAP TO CLEAN STEEL.—A soap for cleaning surgical instruments, and other articles of polished steel which have become flecked with rust by exposure in showcases, is made by adding precipitated chalk to a strong solution of cyanide of potassium in water until a cream-like paste is obtained. Add to this white castile soap, in fine shavings, and rub the whole together in a mortar until thoroughly incorporated. The article to be cleaned should be first immersed, if possible, in a solution of one part of cyanide of potash in four parts of water, and kept there until the surface dirt and rust disappear. It should then be polished with the soap, made as above directed. Articles so treated look as "good as new."

GLASS HAND-WHEELS.—Glass hand-wheels for steam fittings have been recently brought into the market. These are solid disks of black or colored molded glass which has been toughened, and are formed with a square hole for the spindle, on which they are fastened by a nut. Compared with metal hand-wheels they recommended themselves by their cheapness and less conductivity of heat, so that they can be always handled without fear of burns. They are stated to be more durable and cleanly than wood wheels, but it seems doubtful whether they would stand such rough usage.

TESTING IRON AND STEEL.—The extent to which iron or steel should be strained while testing it when made up into a hoiler, a small girder, a bolt, etc., is still a matter for debate, although a sort of general agreement has been arrived at, that the test stress ought not to be less than one-third or more than one-half of the ultimate strength of the material.

PROPORTIONATE WEIGHT OF SHAFTS.—The weight of shafts or bars are to each other as the squares of their diameters. Thus, a two-inch shaft weighs four times as much as a one-inch shaft.

A NEW PIPE JOINT.—A Pittsburg man has invented a joint for cast-iron pipes which proves highly successful, and is expected to revolutionize the system heretofore in use.

SCIENTIFIC PROGRESS.

Influence of Electricity on Plant Roots.

It is a fact generally known to botanists that the roots of aquatic plants incline to one side or the other when an electric current is passed through the water in which they grow. Mr. Elfring was the first to observe this fact, as long ago as 1882. He found that the majority of the roots examined by him curved positively, that is, toward the anode; others, on the contrary, curved toward the cathode; and, finally, some exhibited an inclination whose direction it was difficult to determine. Mr. Elfring endeavored to explain this phenomenon by saying that the current, acting upon the protoplasm, produces a diminution in the turgidness of the cells, and consequently a retardation in the growth; and this retardation being different at various points of the root, there results a curvature of the latter.

A little later, Mr. Brunchorst thought that he had discovered that the curvature depended solely upon the intensity of the current—that is to say, that a current of feeble intensity produced a negative curvature, and one of strong intensity a positive one. More recently some researches on this subject have been made by Mr. Rischewi. According to the theory which he espouses, the curvatures are attributable to cataphoric action. This scientist bases his theory upon the well-known experiment of Dr. Du Bois Reymond, in which two cylinders of coagulated albumen, placed between the electrodes, show an inflation at the negative electrode, and a contraction at the positive. This phenomenon is due to the fact that the water in the cylinder moves, under the influence of the current, in the direction of the latter. Roots afford another example of such action. As the turgidness of the cells increases on the side next the cathode, this side elongates, and a positive curvature is produced. The negative curvature is explained by the diffusion of the external liquid in the porous roots, this occurring on the side next the anode, when a current of feeble intensity is made to pass.

THE EARLY OCEANS.—RED HOT AND HIGHLY DESTRUCTIVE VAPORS.—It has often been a mystery to the uninitiated how such a vast erosive action as evidently took place could have occurred in the very early period of the earth's existence as a partially solid body. The following remarks of Professor Proctor will explain this matter quite to the satisfaction of every intelligent reader: The professor recently remarked that the present denuding effects of air and water are absolutely as nothing compared with the action of the denuding forces which must have been in operation when the earth was young. The oxygen and nitrogen of the air are but a residuum of what was once there. But besides these gases, now in due proportion to support the earth's life, there were immense quantities of carbonic acid gas, of sulphurous acid, sulphureted hydrogen, chlorine, horacic acid, and other destructive gases, some ready to assume the liquid form and so to be still more destructive. But there must also have been immense quantities of water in the form of vapor. The pressure of that primeval atmosphere must have been so great that the waters of such oceans as then existed could have turned into steam only at a temperature so far above the boiling point at the present atmospheric pressure that the surface of the ocean must actually have glowed with inherent luster. The water vapor in the air must have been steam at high pressure and intensely hot. The rains falling then must have been torrents of hot water, impregnated with destructive acids, and falling on intensely heated rocks, ready for most rapid change by the powerful influences of such deluges and of the dense, complicated and destructive atmosphere through which they fell.

THE POLARITY OF TADPOLES.—The following is reported about an interesting experiment of the physiologist, Prof. L. Herman. In a flat bowl filled with water, in which a number of 14-days' old frog-larvæ were disposing themselves, were sunk along the narrow side, ready for an experiment, thick zinc wires connected with a battery of 20 little zinc carbon elements. When the current was made, the whole of the little animals fell into a wriggling motion, which soon ceased. But all the larvæ without exception had taken up one position, in which the head was turned to the anode and the tail to the cathode. The animals remained in this position till the current was again broken, when they again fell into the wriggling motion, but now less violently. Repeated experiments proved that the living animals showed a decided polarity, placing themselves along the stream lines of a current with their heads all in one direction, this direction being reversed when the current was reversed. An explanation of this interesting phenomenon has not hitherto been given.

SOURCE OF ELECTRICITY IN A RAPID CHANGE OF TEMPERATURE.—A correspondent of the *Boston Journal of Commerce* writes as follows in regard to the source of electricity: I have already described some of the various ways by which electricity is generated in factories. I propose to continue the same subject in this paper, for not until this is thoroughly understood can I hope to point out intelligently the different methods that may be employed for its

mitigation. A fan blowing a current of cold air into a hot room is a powerful exciter of electricity, or a fan blowing a hot current of air into a cold room produces equally powerful results. A metallic disk is just as good a generator as glass, provided it is insulated; thus, a circular saw mounted upon a well-seasoned wooden frame, sawing kiln-dried pine boards, will charge with electricity every belt and machine in a large shop, whereas, the same saw mounted upon an iron frame and standing upon an earthen floor accumulates not an atom because it is passed to the earth as fast as generated. I have tried this. A friend of mine, who is a telegraph operator, called my attention one hot summer day to the sparks emitted by the wires. I found these sparks were produced by cold blasts of air from the northwest that occasionally rushed through a long cut some miles north of the office. Thus it may be seen by close investigation that the source of all electrical disturbances is in a rapid change of temperature produced by force of some kind, it matters not which, animal, chemical or the natural forces. As heat produces or liberates heat, so electricity can be employed to generate electricity. And here let me state that heat is not electricity. I am prepared to prove this by a very simple little machine that I made a few years ago that accounts for every atom of heat liberated in the production of electricity. If you place iron ore and coal in a blast furnace, the iron will fuse and run out; but the iron is not the heat, nor is it the coal. No, the iron is iron *per se*. So electricity is electricity and nothing else.

MAGNETIC QUALITIES OF IRON.—It is well known what an influence the quality of the iron in the field magnets has upon the ultimate output in a dynamo, and a case in point is mentioned by Mr. Gishert Kapp, showing how impossible it is to foretell accurately the performance of a dynamo unless the quality of the iron be exactly the same in the manufactured machine as the sample submitted. In the case of two machines manufactured for him, there was a difference of electro-motive force of 20 per cent between the two, although the machines were of exactly the same dimensions and treated in the same manner. It was imagined that in the first machine the iron magnets had not been sufficiently annealed, in consequence of the shortness of time allowed for the work. A second pair of field magnets were ordered and an extra time allowed for the work, the consequence being that 20 per cent more electro-motive force was obtained.

MOVEMENT OF THE WASHINGTON MONUMENT.—At a meeting of the Washington Monument Society, Col. Casey made some very interesting statements to the members of certain observations of the habits of the monument, by which it appears that the great obelisk is a moving, if not a living, thing, and that it has a regular swaying motion when the sun is shining upon it. On every bright day the apex of the monument moves at least one inch westward in the morning when the sun's rays first fall upon it, and eastward again in the afternoon when the sun reaches the western side. The heat of the sun's rays have an expansive effect upon the masonry, and the plummet that is suspended in the interior of the monument registers this movement from day to day.

OCEAN MOUNTAINS.—A French geologist, M. de Lapparent, lately called the attention of the Paris Geological Society to the effect gravitation has in heaping up sea waters upon the land. The continents are thus all situated at the tops of hills of water; and in crossing the Atlantic the ship has first to go down hill, then to cross a valley, and finally to climb another hill. The calculation has been made that in mid-ocean the surface may be more than half a mile below the level it would have been had continents exerted no attraction.

THICKNESS OF CLOUDS.—Captain H. Toynbee, of the London Meteorological Society, has arrived at the conclusion that clouds of not less than 2000 feet in thickness are seldom accompanied by rain, and if they are it is very gentle, consisting of minute drops. With a thickness of between 2000 and 4000 feet the size of the drops is moderate. With increasing thickness comes increasing size of the drops, and at the same time the temperature becomes lower, until, when the thickness is greater than 6000 feet, hail is produced.

INVISIBLE SUN RAYS.—A recent writer on photography and chemical properties of light says: "The experiments of modern photographers have revealed to us extraordinary chemical properties in the sun's rays, while some of these rays are entirely destitute of this peculiar power. It has also been discovered that there are rays of light outside of the solar spectrum, and which are invisible to the human eye, just as there may be vibrations in the atmosphere too high or too low to produce an audible sound."

A NEW GUM SOLUTION consists of two grams of crystallized aluminum sulphate dissolved in 20 grams water added to 250 grams strong gum arabic solution—two grams in five grams of water. Ordinary solutions of gum arabic, however concentrated, fail in their adhesive power in many cases, such as the joining together of wood, glass, or porcelain; prepared, however, according to the above receipt, the solution meets all requirements.

ENGINEERING NOTES.

Eads' Ship Railway.

Eads' Ship Railway enterprises has received a very encouraging lift from the Senate committee of Congress. In its report, presented by Senator Congar, the committee says: "Many of the most distinguished engineers, naval constructors and shipbuilders of the world concur in the opinion that the project is in every way practicable and that the largest ships, with their cargoes, can be safely carried upon a properly constructed railway over moderate grades. From these opinions the conclusion is irresistible that the project is a practicable one. * * * From the surveys it is apparent that the route is entirely practicable for the construction of the proposed road; that there is no swamp land encountered upon the line, and that the harbors are of a character suitable to the wants of the commerce of the world. The committee is of opinion, from a careful study of statements deemed to be reliable, showing the extent of the commerce which would be likely to use a transit way across the isthmus, if constructed, that the net annual revenue of the road will be in excess of the amount guaranteed by Mexico and the United States. It is possible that for the first few years there may be some deficiency to be made up by the two Governments, but such deficiency would be likely to be small, and after the first few years the committee is of opinion that none would exist."

It is not at all probable that the aggregate amount (\$7,500,000) will have to be advanced by the Government. If the road is made an engineering success it will insure such an enormous saving in distance that commerce will certainly avail itself of it.

The committee estimates, assuming that the tonnage will amount to 4,000,000 tons and that the average charge for transporting it upon the railway will be \$2.50 a ton, that the gross revenue of the road will amount annually to \$10,000,000. One-half of this will constitute the net revenue, and if this amount is earned neither our Government nor that of Mexico will be required to pay anything under their guarantee.

The Germ of the Cantilever Bridge.

The germ of the cantilever bridge system is quite ancient, and has been in use for centuries by the natives of Japan, Siam and Tibet, and by the aborigines of Mexico on this continent. This germ, as found both in Tibet and Mexico, consists of trees and vines and is made with a primitive hand hatchet. The first tree on either bank is large and long and extends over a rude stone pier, one-third being on the water side. The other end is weighted by wicker baskets filled with stones and suspended in pits on the shore side. A smaller tree is bound to the first by means of wild grape and other vines and with pieces lashed to the sides of the joint, if need be. The cantilever is rendered stable by additional baskets and stones, until the two sections are united, and a cantilever bridge spans the wild mountain torrent for a foot passage for the natives and for a model for modern civilization.

The following description of a bridge of this kind of a somewhat more pretentious character, constructed by native engineers of Japan, a long time ago, is from *Van Nostrand's Magazine*: "At the sacred city in Nikko the other day, I was rather amused and interested at seeing a fine and very costly bridge of cantilever construction—abutments of hewn stone, shore piers, hewn granite, octagonal, monolithic mortised for stone girders; monolithic plate beam to receive wooden superstructure. The stringers are fastened into the abutments, balance over the stone beam, but do not reach, by considerable distance, the gap being fitted by the middle stringers let into the short stringers. The Niagara bridge is a mere amplification of this one, built before America was settled, as a religious duty, very expensive, of thick, red lacquered work, and, like a bridge of angels, its planks are never profaned by the feet of the laity. But it seems queer-like to come away here to find our new inventions old."

THE PANAMA CANAL ENTERPRISE seems to have withstood the somewhat unfavorable report of the government engineer, and De Lesseps will get the additional aid which he asks for. There has never been any doubt about the possibility of constructing the canal; but it is now generally looked upon as an enterprise which can never pay any reasonable interest on the investment. With the aid of Lesseps' name and popularity, the indications now are that the work will go on to completion. But the wastefulness and extravagance of the management may well be considered by the French authorities in connection with the new loan contemplated. If the Government is to authorize a lottery loan for \$125,000,000 more or less, it certainly owes to the French people some care that the money shall not be wantonly and wastefully spent without reaching its object.

THE SOUTH, according to the *Baltimore Manufacturers' Record*, is about to enter upon an era of railroad building. The present proposals embrace a road south from Roanoke, Va., one from Augusta to Chattanooga, one called Georgia Midland Road, one from Atlanta to the sea coast, and several others which are being worked up with good indications of success.

USEFUL INFORMATION.

Coal Oil Nuisances.

Housekeepers may avoid all the nuisances and discomforts arising from the use of coal oil by thoroughly understanding how to use that useful and indispensable article. A perusal of the following ought to afford sufficient instruction in the matter: Of all misunderstood things in daily life, the use of the kerosene lamp probably stands at the head. First, a lamp is bought and fitted for use, and then filled day after day, and after a longer or shorter period does not give as good light as it used to; then some complaints to the oil man or grocer about the quality of the oil, when a little reason or judgment used would remedy the fault and remove the cause of complaint. If persons using a lamp would remember that the lamp is a machine combining the furnace and pump, and endeavor to learn the principle of using oil, much trouble would be saved; for while no one expects to use a large machine without learning how to work it, any one can use a lamp.

The wick is the pump to bring the oil from the font to the blaze, and as there is always more or less dust and dirt in the oil, the wick soon becomes clogged up and cannot pump oil fast enough for a good light; so a complaint is made when a new wick would remove the cause. Then as we burn oil out the lightest part burns, leaving the heavy oil, and as the lamp is filled day by day the oil gets so heavy that the draft is not strong enough to pump it up, when the oil should all be turned out of the lamp and it refilled with fresh oil. And then the burner, after a time, gets gummed up, and the even flow of the oil is disturbed and causes a smoky, uneven light, which is very vexatious.

When the wick needs cutting some scrape it off, others cut it so uneven that it makes a pointy blaze. The burner is furnished with a great number of small holes to provide air, to the end that perfect combustion may take place, and not to collect dust and dirt until they are all clogged up, and smoky, bad-smelling light is the result. Now, if in using kerosene we fill the lamp up with white oil every day, and once a week empty back the oil which is in the lamp, and use a wick cut even and true every week or once in two weeks, and are sure to have the lamp burner clean, and a clear, nicely polished chimney used, we will find that the kerosene lamp is a great and cheap luxury.

CAMEO CUTTING.—When a cameo cutter is ready for work he draws on the white surface of the stone with a lead pencil the design which he intends to produce in the cameo. He then follows the outlines with a diamond and cuts away the white parts outside. If the stone is small, he cements it on the end of a stick; if large, he holds it in his hand, and proceeds to work upon it with fine drills. He sits at a table like a sewing machine table, and by a treadle works a small lathe situated at his right. At his left is a frame filled with drills made of steel wire and of all varieties and shapes. The ends of the drills are covered with diamond dust ground in olive oil. The dust is obtained by crushing uncut diamonds by blows of a hammer in a small steel mortar. The cutter has placed before him a picture or a small model of the subject to be made. Everything then depends upon the correctness of his eye and his artistic instincts. The work is inexpressibly slow, but when completed it is marvelously perfect.

AN IMPROVED SEWING MACHINE.—There has just been patented a new sewing machine on the rotary shuttle principle, which the inventor, Mr. Waterston, Edinburgh, claims to be the simplest yet made for effecting the lock-stitch. The novelty of it lies in a circular saucer-shaped shuttle, which is set up on edge and laid with its flat side against the left-hand end of the lower shaft, while it is held in position by a revolving cup. The axis of the shaft, the shuttle and the cup, being in line and revolving together, the result is an easy motion far surpassing the old reciprocating shuttle. The machine may be said to be constructed on the rotary system, for nearly every part rotates, which renders, it is said, the motions easy and light and makes it capable of a much higher speed than any lock-stitch machine hitherto in use.

BONNETS MADE OF PAPER.—The craze for utilizing tissue paper in making artificial flowers and other ornaments, which has become so popular with society belles, promises to prove a boon to the citizen of limited means whose wife and daughter have an eye for the beautiful. A prominent society lady has hit upon the novel expedient of making ladies' bonnets of delicately tinted paper with the aid of a few more substantial materials for the purpose of securing strength and durability. Instead of a body of magnificent plush or velvet the framework of the bonnet is of tissue paper, costing about 15 cents, and the trimmings are of artificial flowers, with here and there a strip of ribbon. The effect is unique.

STEAM BICYCLES.—The latest thing in steam bicycles, according to the *Chicago Herald*, is the invention of a New Jersey man. The fluid used is gasoline, and is carried in a tank holding one pint, which is enough to run the engine an hour. The boiler is made of copper and brass, of the drop water tube type, with 14 half-inch tubes 10 inches long. It is a com-

plete boiler, with anti-burning jacket, safety-valve, steam and water gauges, etc. The water-tank is in the form of a globe, and is fitted with a little pump which feeds the boiler. The engine proper, including driving pulley, weighs scant two pounds. The whole outfit weighs only 18 pounds, and it is supposed to carry the rider along at the rate of 12 or 15 miles an hour.

A NEW FLOAT.—After considerable outlay in time and money Mr. A. J. Wright, of Cleveland, O., has succeeded in making a solderless copper float which is claimed to possess in a remarkable degree the essential qualities of buoyancy, strength and durability. These floats are said to stand with perfect ease a steam pressure of 200 pounds without either filling with water or collapsing; and how much more they will bear remains to be seen when facilities for still more rigorous tests are obtained.

DECLINE IN THE PRICE OF MAGNESIUM.—The cheaper method of producing magnesium has recently led to quite a decline in the price. The fall in England has been from \$3.75 to 65 cents. It is expected that the price in this country will fall to at least 75 cents instead of \$3 per ounce as formerly. This great reduction in price will soon lead to a more general use of this metal in the arts.

HOW TO KILL COCKROACHES.—Just before bedtime strew the floor of rooms which they infest with fresh green cucumber peelings, and as soon as it is dark they will come out to feast upon the savory morsels. You may count on poisoning one-half of all the first night. Two or three more feeds will relieve you of their presence entirely.

TO DEADEN SOUND.—In Germany they are now trying a composition of cork, sand and lime, molded into bricks, for the construction of light partition walls. It is said to exclude sound better than ordinary brickwork, while being light and a good non-conductor of heat.

CLEANING BRONZE.—Recent experiments have shown that treatment with potassium cyanide, followed by washing with an abundance of water, is the best means for removing the incrustations on bronze statues.

THERMOMETER TUBES have to be seasoned. This requires a year or two. When glass is new it changes, expands, contracts and warps almost as badly as green wood.

GOOD HEALTH.

A Small-Fruit Dissertation.

MESSRS. EDITORS:—If we paid our doctors as the Chinese do, so long as we enjoyed good health, and heat them, as they do, when we got sick, we should not be so distressingly dyspeptic. A similar course applied to school-teachers (pay for imparting true science, and stick for retailing nonsense or nonsense) might produce a rising generation wise as serpents and harmless as doves.

For instance, we profess to instruct our youngsters in all the ologies, and somehow neither we nor they regard the simplest rules of health. Take the modes and times of fruit-eating, for example. There's a wise old saw of our grandmothers as to apples being "gold in the morning, silver at noon and lead at night," which applies more or less to all fruits. And the modicum of comparative physiology any text-book gives enables us to see the rationale. We find that herbivorous and frugivorous animals are provided with a much more cumbersome and complicated digestive apparatus, and a much greater length of intestine, than creatures omnivorous. This for the obvious reason that their food is slower of assimilation. Now, a man goes to bed to rest and recuperate, not to keep his digestive organs hard at work to the annoyance of his nerves with a visitation of nightmare. Obviously, then, things difficult of digestion, such as fruits and vegetables, should be eaten in the early part of the day, and not at night.

It should also be remembered that all foods affect the digestive system in two ways—mechanically and chemically. Take, for example, the strawberry. It contains what is known as fragranic acid; producing a chemical effect on the accompanying food; while the numerous seeds affect the mucous membrane mechanically, and have the stimulating effect ascribed to the coarser parts of oatmeal and graham flour. This makes berries of all kinds specially valuable as articles of diet to many. Oranges or other fruits, of which only the soft pulp is swallowed, contain acids of various kinds (oranges, citric; apples, malic; peaches, prussic or hydro-cyanic, etc.), but lack the membrane-stimulus of the small seeds.

Often the benefit derivable from fruit is neutralized by a too free admixture of sugar, causing hilloiness, which is not infrequently attributed to the fruit.

In tropical countries the golden rule to avoid fever is to eat freely of fruit in the morning, but not a taste after midday.

EDWARD BEEWICK.

Carmel, June 6, 1886.

REMOVING OBJECTS FROM THE EYE.—We find the following in an exchange, and offer it for those who desire to try the experiment. Here

is one way of removing objects from the eyes: Take a horse-hair and double it, leaving a loop. If the object can be seen, lay the loop over it, close the eye, and the mote will come out as the hair is withdrawn. If the irritating object cannot be seen, raise the lid of the eye as high as possible and place the loop as far as you can, close the eye and roll the ball around a few times, draw out the hair, and the substance which caused the pain will be sure to come with it. The method is practiced by axe-makers and other workers in steel.

The Effect of Alcohol.

Dr. J. G. Jewell, superintendent of the Home for Inebriates, recently gave a lecture on the effects of alcohol on the human body, in the course of which he first mentioned some of the adulterations which are found in liquors, and which have serious intoxicating effects. Alcohol is the intoxicating ingredient in all spirituous liquors. It is a deadly poison to all plants and animals. The part of a leech dipped in alcohol becomes paralyzed forever. Alcohol injected into a frog with a small hypodermic needle will kill it in a minute. If half an ounce of it be injected into a dog, he will be dead before the needle is drawn out. Any man not accustomed to the use of liquor, who drinks six ounces of alcohol, will almost immediately die. Why, then, do hard drinkers live? asked the lecturer. The poison works slowly in them, he said. They die before their time. The liquor at bare is usually diluted with water. The drinker gets only about 25 per cent of the alcohol. Experiments have shown that there is an immediate congestion of the walls of the stomach when alcohol enters. Alcohol being an antiseptic prevents digestion. Hence every drunkard must become dyspeptic. Chronical colic produces inflammation of the stomach. The action of the stomach being suspended, the drunkard will not partake of food.

At the Home of the Inebriates the lecturer said he had seen drunkards vomit half of an ordinary bottleful of blood a day. Alcohol is a desiccator. It produces great dryness and thirst. Hence those who have imbibed it cool their thirst with beer, which influences the full flow of blood. Hence it is dangerous for drunkards to be wounded or cut. The drunkard, he said, is a hundred per cent more liable to accident, disease and death than the temperate person. Alcohol also hardens the brain, enlarges and changes the liver, and interferes with the proper action of the lungs.

INFLAMMATION IN EGGS.—There is a condition of the egg, little known, which considerably impairs its sanitary value as an article of food. Soon after it became the practice to transport eggs in large quantities and to long distances by railway trains, it was found on their arrival that adhesion had taken place between the membranes of the yolk and those of the shell, so that the yolk could not be turned out of the shell unbroken. On examination by experienced pathologists this was found to be the result of true inflammation; the material of the adhesion was found to be precisely the same as that of the plastic exudation in inflammation of the lungs or bowels. It will at first seem absurd to speak of inflammation in such an unformed mass as an egg, but this arises from our forgetting that, structureless and unorganized as it seems, the egg, even when fresh laid, is a living being, and capable of disease from external causes. The cause of this inflammation is undoubtedly the shaking and friction from the motion of the cars, and it cannot but render the egg more or less unhealthy, as the products of inflammation can never be as salutary in food as those of healthy growth.—*Bulletin of the Tennessee Board of Health.*

CLOTHING OF THE SKIN.—Dr. Startin, in a paper on the health of the skin, says: "A very prevalent habit exists of putting too many wraps upon the skin. No man's skin, or woman's, either, can be kept thoroughly clean and healthy by piling too much clothing upon his or her body. It is a fact that clothing in itself has no property of bestowing heat, but is chiefly useful in preventing the dispersion of the temperature of the body, and in some instances in defending it from the atmosphere. This power of preserving heat is due to the same principle—that of conduction and non-conduction—whatever form the raiment may assume; whether the natural covering of birds or animals, or whether the most healthful and elegant tissues of human manufacture."

ICE IN THE SICK-ROOM.—A correspondent of the *National Druggist* makes the following seasonable suggestion: "The writer's son suffered with typhoid fever during the heated term of last summer, when the temperature of the room often rose to 90° or 95°, and the patient's temperature ran up to 105° F. and over. A number of tubs were placed in the room, and kept filled with ice, and the doors kept closed. The temperature of the room sank to 80° or less, an average of 12° or 15° below the temperature of the other rooms in the house, and a cooler atmosphere not only added to the comfort of the patient but also aided in keeping down the body temperature and materially contributed to final recovery."

It soothes a feverish patient to bathe with warm water in which a little eucalyptus has been dissolved.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

LOYAL LEAD.—*Ledger*, June 19: There is scarcely a mine on the main belt having a more promising outlook to develop into a permanent-paying property than the Loyal Lead. It has been owned for the past four years by a company of 10 persons, all working miners and comparatively poor men. The ground owned by them includes the Pennsylvania, the adjoining claim on the south, both mines embracing 2080 feet along the mother lode. Under the present company work has been confined to the Loyal Lead claim. The development has been by means of two tunnels, the lower one, which is now being used, tapping the ledge about 80 feet from the surface. They have followed the ore body north and south, a distance of 115 feet, with ore at both ends. The ledge averages 15 feet in width, the whole of which is sent to the mill. A steady improvement in the grade of the quartz has been noticed as depth has been attained, with a large increase in the percentage of sulphurets. The rock is of a live character, a fair sample of which has been left at this office, showing several specks of free gold. A 10-stamp mill is kept running steadily. The stamps are light, however, not crushing more than an average of one ton per stamp per day. Some idea of the value of the claim may be gathered from the fact that during the past four years, working with very limited facilities, they have paid \$2,000 for the claim and erecting the mill, besides drawing \$3 per day per man as wages. For the past six months the rock has averaged \$6.15 per ton, exclusive of sulphurets. Some of the crushings have yielded over \$10 per ton. It is claimed by those best qualified to judge that there is ore enough above the tunnel level to run a 40-stamp mill for at least four years. The present owners are not able to put up the necessary machinery to develop the property on a scale which its present and prospective merits would justify.

MISCELLANEOUS.—Jason D. Wheeler has bonded the Doyle quartz mine, in Hunt's gulch, for the sum of \$15,000, to be paid on or before the first day of October next, the work of development to be commenced within 30 days from date of agreement. The Gover continues to look well. Eight more men were put to work last week, which fact alone speaks well for the prospects of the mine. The Lighthouse mine, near Butte City, has come to a standstill, with no prospect of work being resumed under Mr. Flagg's management. It is expected that the property will fall into the hands of Ginochio Bros. V. P. Yelmini is running 10 stamps of the Oneida mill on the old dump pile, which is said to yield a small profit over working expenses.

NOTES.—Amador *Sentinel*, June 19: We understand that the capacity of the Zeile reservoir is to be increased by raising the banks two feet. Mr. Wheeler, a well-known mining man, has bonded the Doyle mine, in Hunt's gulch, for \$15,000, with the intention of commencing work upon it. We trust this experiment will result in a more permanent investment than is usually the case when a bond is taken.

SUTTER CREEK.—*Ledger*, June 19: The 10-stamp mill purchased by the Iowa Company has all been hauled from Angels here. S. Breeze has got the job of putting it up. The old five-stamp mill has been taken down.

Calaveras.

KELTZ MINE SOLD.—*Calaveras Chronicle*, June 19: We are reliably informed that the Keltz mine near West Point has recently been sold to a San Francisco company for \$10,000. Mr. O. B. Peasley, one of the owners and the superintendent of the mine, informs us that a shaft has been sunk to a depth of 180 feet and crosscuts made, showing a well-developed body of ore very rich in sulphurets, and upon the very favorable developments made resulted the purchase of the mine.

El Dorado.

TUNNEL.—*Placerville Observer*, June 19: Superintendent Henry H. McClellan has got the lower tunnel at the Melton mine, Mountain township, in for a distance of 600 feet, and notwithstanding the rock is very hard, is pushing it at the rate of 25 feet per week. He will drive the tunnel something over 200 feet before starting up the mill again. They have rock enough in sight to-day to run the mill for a year, but Mr. McClellan says he is going to know just what there is to the Melton mine before he makes a new move. The Eagle King mine, under the superintendence of Jonathan Camp, is being vigorously worked, and the ore being taken out gives promise of a bright future for the property. The mine is located in Mountain Township, and arrangements have been made for crushing 100 tons of rock at the Mount Hope mill, the result of which crushing will probably settle the question of erecting a mill on the Eagle King.

Fresno.

FRESNO MINES THE BEST.—*Fresno Republican*, June 19: About the first of March last McDonald Bros. sold the Surprise mine near Grub gulch for the sum of \$60,000—a neat little fortune in itself. The purchasers were Tom Ewing and D. B. Gillett, who are now working the mine with increased facilities and making it pay handsomely. Shortly after this sale the Messrs. McDonald made an extended tour through the principal mining districts of Northern California, Idaho, Montana, Colorado and Wyoming, and from there they went to the Atlantic States, where they visited relatives and friends. Returning to California over the Southern route, they arrived at Fresno the 25th of last month. Their trip through the northwest was made with a view to finding a new location for mining, but after a thorough investigation they came to the conclusion, all things considered, that Fresno county is a better field for a legitimate mining business than any other section of the country. With this fact definitely fixed in their minds they are again actively at work. They have, since their return, in company with Mr. E. W. Chapman, commenced the reopening of the old Nat Harbert mine and are also at work upon a new location in Fine Gold, known as the Lewis mine. It is expected that both mines will be pro-

ducing by the first of January next. The success of McDonald Bros. in quartz mining in this county is one of many cases which attest the increasing richness of Fresno mines. We believe there is not a mine in the county which has been worked to a depth at which good returns may be expected which is not now paying property, and some of them are paying more on the capital invested than any other business enterprise in the country.

Humboldt.

ALONG THE KLAMATH.—*Humboldt Standard*, June 16: On Saturday last we had an interesting talk with T. W. Reece, mining engineer and deputy U. S. mineral surveyor, who has been operating a gravel mining claim during the past year at Big Bar on the Klamath. From him we gather the following facts relative to gold mining along the river: J. A. Perch has had from eight to twelve men at work since last November. His claim has paid well. Mr. Markham, just above Orleans, has had a profitable season. Henry Wilder has done well on his claim. The McBrown claim has been operated during the past season under the direction of W. H. Hamilton, from San Francisco. It is rumored that Mr. Hamilton represents a San Francisco syndicate and is now testing this claim in their interest, and should it prove satisfactory ample capital will be provided to work this claim to the full extent of its capabilities, having at hand every modern facility to extract and save the gold. So far it is believed the result of Mr. Hamilton's investigations have exceeded his most sanguine expectations. Mr. Reece has just completed a survey for a ditch for this claim which will bring in 2500 inches of water. The construction of this ditch will be commenced as soon as a favorable report is handed in by Mr. Hamilton. Fred Wilder's claim, next to the McBrown, has been operated under a lease by other parties and has doubtless proved profitable to them. The Red Cap claim has been operated by Lord & Allen. This bar, at the mouth of Red Cap creek, has paid well notwithstanding the many setbacks which have occurred. Lord & Allen have also operated the old Bristol claim, this season. The yield at this latter claim has been very remunerative, astonishing all, even those who were the most sanguine as to its merits. Big Bar, which in years past has been celebrated for its good yield, has been worked this season, but has not been remunerative. Saint's Rest claim, owned by Mr. Falk, of Arcata, but under lease to William Lord, has been operated and it is believed has paid well. At Witchepek, Frank Brown and Wm. Lord have been working all season and it is believed have made money. Below Martin's Ferry Captain W. J. Young has been working his mining ground, but with what results our informant has not been able to state. The Peckwan has been operated by William Lord and it is generally thought that the claim has paid. The past season has been the most favorable for mining operation on the Klamath that the mines have had for several years past. They have had plenty of water. The season began by the first of November and the water will be available on most claims until the middle of July. From the above facts it will be readily seen that gold mining is quite an industry in Humboldt county, and as population increases it will beyond question be extended. There is much ground along the Klamath and Trinity rivers and their tributaries, yet untouched, which would pay good wages if judiciously worked. Perhaps no great fortunes would be made, but men could live and earn a fair compensation besides. It is only one of the many industries awaiting the help of willing and active hands to be turned to profitable account.

Nevada.

NOTES.—*Grass Valley Union*, June 19: The Crown Point mine continues to produce good pay ore upon which the mill is running regularly. The Slate Ledge mine is also producing good ore which is being crushed at Perrin's mill. A ledge of good quality is showing in the tunnel of the Perrin mine. The shaft of the Boston mine is down 90 feet below the 230 level. The rock coming out of the shaft shows well in free gold. Drifts for a new level will be turned in a few weeks. The 230 level shows well as usual. No trouble is experienced now in banding the water. The Prescott Hill mine is yielding good pay rock all the time, which is crushed at the Orleans mill. The new mill of the Empire Company is gradually approaching completion. It will be the finest structure of the kind in the district. It will be run by water power under pressure.

Placer.

LOVE JACK MINE.—*El Dorado Republican*, May 18: We received a call last week from D. C. Lewis, one of the directors of a company which was incorporated on the 15th of last month for the purpose of developing this mine. The "Love Jack" is situated about four miles south of Greenwood, on the road to Garden Valley, and is on the same lode as the Esperanza, Belle and Rosencrans. Two shafts are sunk on the ledge, one of 40 feet and the other of 20 feet in depth. These show that the ledge is over 23 feet wide, and it is believed that the rock will average over \$6.00 to the ton. Owing to the great size of the ledge and the abundance of wood and water, the expense of extracting and milling the ore will be very low. The superintendent, N. D. Burlingham, is arranging for the erection of a 10-stamp mill, which will soon be set to work on ore already extracted.

THE CHINESE MINERS.—*Placer Republican*, June 12: A friend writes from Gold Run that that town is holding its own with most other mining towns. He regrets, however, to see so many mines falling into the hands of Chinamen. The Indiana Hill Mill and Mining Company's claim was sold to Chinamen recently, and they have employed Mr. W. K. White, an experienced miner and old resident of that locality, to superintend it for them. They are going to put this mine in first-class order and work it for all it is worth. We agree with our correspondent that it is bad to see the mines going into the hands of Chinamen. It would be far better that they should be idle for the present than that their treasure should be extracted by Chinamen and lost from our country and people forever. The mine the Chinamen works to-day, if let alone, would afford remunerative revenue some day for our own people. But the owner says, to put it in the shape of a bull, that he can't wait for a living until after he is dead, and as he is stopped from working his mine himself, he becomes desperate, and sells to the highest bidder, and the Chinaman can afford to offer the most because he can evade injunctions the best.

Plumas.

EAST BRANCH.—*Cor. Plumas National*, June 19: I will endeavor to give you a few items from the East Branch and North Fork of Feather river. Ted and Gene Whiting are hard at work and report fine prospects in the famous French Ravine quartz mine. Good luck to the boys. Tom Johnson is running a tunnel on Mill creek, and expects to strike it rich in the near future. Charles Fitch is ground sluicing in French Ravine, with a favorable outlook. S. L. Scott and S. Richwine are working on Rich Bar. They have some good paying ground and look bappy. Frank Evrand and Ligier, of Indian hill, had a splendid run this season, and their mine always pays well, but since they have been forced to stop pipping they look as though they were ready to swallow the whole of Sutter county. Keep & Co. are hard at work on Indian Bar, bottoming up their ground, and expect a good clean-up this fall. Mori & Lott's mine is lying idle for a short time. Black & Gamble, of Long Bar, are working ground that pays \$4 or \$5 to the pick.

San Bernardino.

MINNETONKA DISTRICT.—*Calico Print*, June 20: This mining district is situated about 30 miles south of Cadiz, on the A. & P. Railroad, and the mines about 15 miles from Twenty-nine Palms. The Virginia Dale Mining Company have several gold mines there from which they have taken out considerable ore, sufficient to induce them to erect a cannon-ball mill, which while in operation reduced the ore satisfactorily, but is deficient in capacity, not milling more than four tons of rock, under favorable circumstances, in 24 hours. The company, after a thorough test, found that they could not profitably reduce the ore with such a mill, and consequently recently suspended operations in the mine and mill until they can put up a stamp mill. It appears that other parties are trying to purchase the property, and the present company may sell their interest in the mines of which they are part owners. These mines are among the finest gold properties in the country. An abundance of water has been obtained in the company's well. When the proper reduction works are erected and the necessary capital expended in developing the mines the output of bullion from the same will undoubtedly be prolific.

About six miles from the company's mill is a group of silver-bearing mines owned by about a dozen parties. Among the fortunate owners of several claims are the Karns Bros., proprietors of the St. Charles hotel, of San Bernardino. We saw some good looking ore from their claims, containing brittle silver. The ore from these mines contains some gold and galena, but principally silver. According to samples made the ore averages about \$75 per ton. The ledge is large and well defined and extends through the group. A shaft has been sunk 50 feet, where the quality and quantity of ore is sufficient to warrant further developments. The boys are sinking as fast as possible, and are very much encouraged over the prospects before them.

Shasta.

DOG CREEK.—*Shasta Democrat*, June 16: I take pleasure in writing you a few lines in regard to the mines on the south fork of Dog creek. There have been several good strikes made here in quartz in the last few weeks. Messrs. Carter & Coyle have one of the finest prospects that I have seen in Shasta county. This mine is located on the headwaters of the south fork of Dog creek. It is a contact vein, the foot-walls being of porphyry, the hanging wall slate. The vein is on an average of three feet in width; it is ribbed quartz and carries some galena. The rock will mill \$20 in free gold; besides, the sulphurets are very rich. This ledge has every indication of going down to a great depth and carrying gold. There is a belt of country running from the head of South Fork to Clear creek, where there will be some more good ledges found.

IGO.—The machinery of the Chico mill is on the ground, and is being put in place. It consists of an eight-stamp Redstone Patent mill, with rock-breaker, and two Duncan concentrators, to be run by a six-foot Pelton wheel. The tunnel on the Dayton is progressing as fast as the nature of the ground will permit. The ore body has not yet been reached. E. L. Ballou's arastra is running on Hope ore, and more are being taken from the Manzanita. Hubbard & H. Shirlan are taking out ore from the Pacific, and running the same through the Meek arastra. J. P. Wright is running his arastra and taking out ore from his mines. F. Shirlan & Russell are running the Chicago mill on South Chicago ore. J. & E. Blank are taking out a run of ore from the North Manzanita.

WHISKY TOWN.—*Cor. Shasta Courier*, June 12: Now that the summer time is advancing and prospects look favorable for the future, I will endeavor to give you the latest from our little burg. Bradbury & Co., of Red Bluff, are developing some fine-looking mining property on Mad Ox. Their location lies directly north of the Mad Ox mine, and is surely a credit to that vicinity. The company have several men employed at the present time, and are taking out ore as fast as circumstances will permit. Their ledge averages from 18 to 24 inches in width, and is all classed as high-grade ore. Jackson Ferguson is taking out some good ore from his mine on Whisky Creek. He is contemplating the erection of a stamp mill on his mine this summer. A. W. Hawckett & Co. are drifting for gravel mines in Mad Mule Gulch, but have not completed the drift to where they expect to find their pay gravel. Kernel Mead and Robert Warfield are running a tunnel on the old Phoenix mine. They are in hopes of finding paying ore in the southern part of that location.

Sierra.

PURCHASED.—*Mt. Messenger*, June 19: The American Hill quartz property has been purchased by the Pilgrim Co., the purchase price, \$16,000, having been paid to Judge Van Clief a short time ago. Stephen Moore, the new superintendent of the Young America mine, has had long experience, having been superintendent of some of the best mines on the coast.

Trinity.

DEADWOOD.—*Cor. Shasta Courier*, June 19: Mr. McKibbins, a mining man well known in Colorado and Montana, has been prospecting around here for the last month or two, and after making some assays he bonded the North Fork mine, between the Monte Cristo and Eagle mines—the latter owned by John Harries and Mat. Chadbourne—for two thousand dollars. He has taken in two partners, T. Slattery and J. Reynolds. They have commenced extracting

ore and made arrangements with the Dreadnaught Company for its reduction when their mill is completed, which they expect will be about the middle of next month. Frick & Davis are running out excellent ore, and have about 75 tons on the dump ready for milling. Work in the Brown Bear mine is going on as usual, but the clatter of the stamps is not heard although the millmen have all they can do to renovate and thoroughly overhaul everything preparatory to a fresh start after the 110th anniversary of our independence. The new boiler is in its place and the cylinder has been sent to Marysville to be bored; also the shaft to be straightened. To expedite matters Superintendent Martin left for that city last Saturday, and will not leave until everything is shipped for the return trip. Time means money in this case. Two more concentrators are to be added, and the 15 stamps will soon be music in our ears. The Little Gem mine, belonging to Gibson & Leavitt, is still turning out rich rock, and keep their cannon ball mill moving. Balleau & Co. have 16 men at work chopping wood and moving their mill. They mean business when they start.

MORE QUARTZ.—*Trinity Journal*, May 19: Jas. M. Moore was in town from East Fork this week. From him we learn that John Day and himself are building an arastra to work ore from the Engle mine on Rich gulch, and that prospects are most flattering. James Daly, in connection with Moore & Day, has found a mammoth ledge on the east fork of East Fork, about 20 miles above the mouth of the latter, which promises well. It is six feet between walls and carries free gold, galena and galena sulphurets.

NEARING THE END.—Miners in Weaver basin are preparing for the final cleanup for the season, as water for hydraulic mining cannot last but a few weeks longer. The season's run has been an excellent one, as results will show.

BIG PAY.—The Venicia mine of Eastman gulch, owned by Mr. C. L. Blakemore, is maintaining its well-established reputation for richness and extent. A cleanup last week from 53 tons of rock produced 357 ounces of gold, or at the rate of over \$100 per ton. And there is said to be plenty of just as good ore in sight.

NEVADA.

Washoe District.

CHOLLAR.—*Enterprise*, June 19: The desired depth of 50 feet for a sump having been attained below the 3200 level, further sinking was discontinued day before yesterday, the total depth of the shaft from top to bottom being 3250 feet—the deepest vertical mining shaft in the world. The bottom is well into the eastern portion of the main ore channel, the material being vein porphyry, clay and quartz, carrying a small amount of mineral with no increase of water. Yesterday morning opening the station for the 3200 level was commenced on the west side of the shaft. When this is completed a lateral drift north will be started to connect with the drift coming south from the Hale and Norcross deep winze, and subsequently a drift west will be started to crosscut and explore the vein at that point.

CROWN POINT AND BELCHER.—Last Saturday morning the fly-wheel of the main hoisting engine at the Crown Point shaft broke, causing a sudden suspension of work in both mines. About 50 miners have been employed extracting ore from the 1400 level of the Belcher, a single hoist engine being used at the shaft. The breakage of the main engine was caused by the gradual settling of the ground at that point from the workings of the Kentucky mine, near by, as well as in the Crown Point, throwing the engine out of line. It is being properly lined up and substantially reset, a broken pillar block replaced by a new one, the other damages repaired, and it is now thought that the full force of men—over 200—will be put to work again next week, extracting the usual amount of ore as before the accident.

ALTA.—Very little advancement has been made during the week in the north lateral drift on the 700 level by reason of the ground near the Lady Washington shaft being considerably broken and loose, requiring substantial timbering. This work is now completed, and connection with the shaft is expected to be made to-day, there being but 10 feet or less of intervening ground to be excavated. This connection will be of great benefit, giving a good and much needed circulation of air throughout the Alta, and when fully completed crosscuts west will be started to explore the good ore vein along which this lateral drift has been skirting.

HALE AND NORCROSS.—On the 3200 level the main lateral drift south to connect with the Combination shaft is now out about 125 feet, and has 140 feet to go in order to connect with the Combination shaft or station being opened for a drift north to meet it. On the 2900 level the diamond drill sent out from the face of the main north lateral drift toward the Savage shows sulphurets among the drillings, indicating some ore in that direction. After the drift has been sufficiently advanced crosscutting will be done from it, with good prospects of finding a paying ore body.

SAVAGE.—The main lateral drift south on the 600 level is in 270 feet from the Gould and Curry south line and continues in fine-looking vein material, principally quartz carrying streaks and bunches of good ore. The crosscut east has cut through several stringers of ore giving high assays, yet none of sufficient size to constitute a paying proposition. They seem to show best to the southward, and another crosscut may show up the main body to which they evidently belong.

CON. CALIFORNIA AND VIRGINIA.—Daily yield about 400 tons from the several ore-producing sections from the 1850 level up to the 1200. The average value of the ore milled is about \$10 per ton, as indicated by average assays from battery samples. Among the other explorations for ore at various points is a southwest drift recently started on the 1650 level to go after known deposits in that direction.

SIERRA NEVADA.—On the 520 level the north lateral drift from crosscut No. 2 has been extended 60 feet, making a total length of 138 feet. The excellent progress made in this drift is owing to the favorable nature of the ground, the material being soft vein porphyry, clay and quartz. A few men are kept employed extracting some pretty good gold ore from the croppings of the mine on Cedar Hill.

BEST AND BELCHER.—The water in the Osbiston shaft was lowered seven feet, leaving nine feet further

to go in order to reach the track floor of the 2319 or bottom level. About three feet of the upper portion of the station is exposed, and the lowering of the water must necessarily be slower hereafter, as there are about 4000 feet of submerged drifts now to be pumped out at this point.

GOULD AND CURRY.—The further advancement of the upraise incline above the 500 level has been suspended for the present, and crosscuts east and west started from it 50 feet above the 500 level. These are now in respectively 28 feet east and 38 feet west. Both are in very favorable vein material—vein porphyry and quartz, giving low assays.

YELLOW JACKET.—About 140 tons continues to be the daily yield. This ore is principally low grade, with occasional streaks and bunches of a better quality. The concentrators at the Brunswick mill operate very advantageously on most of this ore taken from below the 400 level.

POTOMAC.—The new diamond drill hole, started since last report, 75 feet further north from where the other drilling was done, has penetrated east a distance of 65 feet, 25 feet of which is solid quartz, carrying a small amount of mineral.

OPHIR.—Work in and through the shaft has been suspended in order to thoroughly overhaul the hoisting works and surface machinery and put everything in a complete state of repair throughout.

KENTUCK.—The old workings continue their daily output of 60 tons of low grade ore, the various stopes and breasts holding out well.

MONTE CRISTO.—The west drift on the 150 level from the new shaft is still advancing in hard material.

Columbus District.

MOUNT DIABLO.—The stope below the west drift, on the fifth level, looks well. The intermediate stopes between the fourth and fifth levels are looking well. We have two stopes between these levels that show over three feet of \$70 ore. The stope above the west drift on the fourth level shows 18 inches of \$60 ore. We are sinking on a small bunch of quartz near the No. 2 winze, between the third and fourth levels, that looks favorable for opening. We are getting a small amount of ore of fair grade above the west drift on the third level. The intermediate stope below the third level, east of the shaft, is yielding a small amount of high-grade ore. We have started to extend a crosscut from the intermediate, between the second and third levels, to prospect the ground below the east stope on the second level. This stope looks about the same as do the stopes above the second level. These stopes are now turning out considerable ore. Bullion shipment June 8th, \$7773.41.

Hawthorne District.

AT WORK.—Walker Lake Bulletin, June 15: Work will soon be resumed in the deep shaft of the Dictator. A crosscut will be started at a depth of 100 feet. A crosscut was started in the North Star shaft, at a depth of 42 feet. After running 20 feet the foot wall was encountered. The ledge of quartz is three feet wide. Another crosscut is to be started toward the hanging wall. The Hindley Co. will declare a dividend in a few days of seven dollars per foot. The bar of bullion shipped from the Lapanta last week was valued at about \$4000, from 54 tons of ore worked at Cat Creek mill.

Jackrabbit District.

ONANDAGO.—Pioche Record, June 15: The Onandago mine of Jackrabbit, we learn from Henry Welland, who was out there on Sunday last, is looking fine. The ore vein is now about 18 inches in width. Everything about this mine indicates a body of ore near at hand, and only depth will determine this fact. This property has not been worked altogether as it should have been. Later.—From Pat McDonough, a disinterested party, who returned from Jackrabbit on Thursday, we are informed that they struck a handsome body of ore in the mine the first of the week. The ore is between three and four feet in width and solid. On the sides of the ore the ground is loose and somewhat broken, being spar, lime and iron mixed. They are just on the top of it. As yet there have been no assays made of this ore. In character it is about the same as that taken out above. According to description, this mine is destined to become a valuable piece of mining property.

Morey District.

GOOD PROSPECTS.—Belmont Courier, June 14: There are several men prospecting the mining claims at Morey. Recent reports from there speak well of the prospects of that camp.

Northumberland District.

PROSPECTING.—Belmont Courier, June 14: Neil McLeod is prospecting in Northumberland. There are good mines in this district which are bound to come to the front in the near future.

Philadelphia District.

UNDEVELOPED.—Belmont Courier, June 9: Philadelphia district may be said to be still in an undeveloped state as far as its mines are concerned, and although hundreds of thousands of dollars have been spent in their working nothing is known of their value and extent below water. Grass root mining has absorbed the attention and the coin of the management and stockholders so far—with what profit is best known to themselves. Most of the mines of the district were rich and productive on top, and there is every reason to presume that they will continue so with depth. The veins carrying the silver go below water, but they are unprospected. Mining men of experience claim that the mines of East Belmont as soon as properly opened and worked below water will be among the most productive and remunerative in the State. It will take heavy machinery and capital to demonstrate this fact—and it is sure to prove a profitable investment. Most of the bullion of the Comstock came from below water, and there is more left to take out yet undiscovered.

Pioche District.

PLENTY OF MEN.—Pioche Record, June 14: Now that work on some of the mining property in Pioche is about to commence, we would not advise all the idle men in the country to come to Pioche for work, or they will be doomed to disappointment. There are a sufficient number of men here at present to do all work required. The toot of the Raymond & Ely whistle was heard on Thursday, the first time for a

great while. Engineer Stoddard has not forgotten how to play on the instrument. Fifty tons of manganese ore from what is supposed to be the croppings of the Raymond & Ely, in Pioche, has been chloridized in the B. S. Company's Stedefeldt furnace, the chlorination averaging 85 per cent. This ore, or croppings of ore, without assorting, averages 18 ounces in silver per ton. So far the lixiviation process has proved a failure on Bullionville tailings, and it is more than probable that they will be left to the chloridizing influences of the elements until scientific research has discovered in the laboratory of mineralogy something that will materialize their rebellious character. The future for Pioche looks much brighter than it has for a long while. A number of men, during the week, have been placed at work calking water tanks, and doing other work necessary for the resumption of active operation in the mines. What will be the name of the new company that is about formed, we did not learn, but are informed that most of the stock has been subscribed. Mr. L. D. Davis, an experienced and thorough miner, who in years gone by has worked in the principal mining camps of this State and California, has been appointed foreman of the company, and is doing all that lies in his power in having all works placed in readiness, but it will take considerable time yet before this will be accomplished. After completion of arrangements by the company, work will then be prosecuted with vigor.

Reveille District.

EXCELLENT INDICATIONS.—Belmont Courier, June 14: We learn from Ed. Cavanaugh that the work of prospecting the various claims at Reveille, Nye county, is progressing with energy. The Gila mine is looking well, and good quantities of rich ore have been extracted. The indications are excellent for uncovering big bodies of ore in this mine. The mill is receiving the finishing touches, and it is expected that it will start up on ore from the Gila mine on the 5th of July next. The Norris Brothers, Joe Bianchi and others are also working on their properties, and the chances for extracting rich ore from their claims are splendid. In fact, Mr. Cavanaugh is of the opinion that the mine-owners of that district will be rewarded for their labors before the end of next summer.

Trinity District.

MINES BONDED.—Silver State, June 16: Some 18 mining locations in what is known as Arabia, in Trinity mining district, have been conditionally sold by George Lovelock to James Duncan, of San Francisco.

Tybo District.

ENCOURAGING.—Cor. Belmont Courier, June 14: The prospects of Tybo making another boom are very encouraging. After persistent prospecting by the indefatigable prospector, W. D. Dimick, the westerly continuation of the once bullion-producing 2-G vein has been discovered and work of development commenced. A shaft down 10 feet shows a vein of ore 12 to 14 inches in width, increasing as depth is attained. The ore is precisely the same as that extracted from the 2-G vein in its palmist days, showing that it is the same belt. Assays run from \$50 to \$225 in silver, carrying in gold \$4.10 to the ton. The ledge can be traced along the surface for 400 feet, showing croppings of rich ore in several places along the vein, the course and pitch of the vein being the same as 2-G. This new discovery is known as the "Ma Alta" claim. On the east end of the 2-G vein comes the "Comet," located by Capt. George Turin. This claim is looking very encouraging. A tunnel 98 feet in length, the face of which is in porphyry, denotes a close proximity to the vein. This claim lies 300 feet, more or less, east of the famous Garrett Chamber, which produced \$1,000,000 at the time that the Tybo Consolidated Mining Company had the furnaces in full blast. The G. F. mine, owned by the Gilmore Brothers, is looking splendid. They are sinking a shaft on the vein and have a very good prospect. The ore is somewhat different from 2-G ore, carrying no lead; in fact, it is a fine milling ore; assays run from \$40 to \$260 per ton. They have from 20 to 30 tons of ore in sight. What is now needed to restore good times in Tybo, once more, is a strong company or syndicate that will take hold of the above-named properties, and cause bullion to be shipped as freely as in the early days.

ARIZONA.

NEW REDUCTION PROCESS.—Tombstone Democrat, June 19: John P. Clum, Richard Rule and Ed. Wilson are busily engaged in preparing works for the reduction of ores by the Rule-Wilson process, which is the result of much study and a long series of experiments on the part of the inventors. It has several points of superiority over any other known process. It is cheaper and works the ore closer, and is beside used with success upon the most rebellious ores. Messrs. Rule and Wilson are confident of ultimately realizing a fortune from the process, the only drawback at present being the necessity capital to put up a plant and start the works going. The Democrat trusts their brightest hopes may be realized.

COLORADO.

MORNING STAR.—Georgetown Courier, June 19: Forrest & Hogan, lessees on the Morning Star lode, Republican mountain, are drifting west from the bottom of the shaft on a vein of nearly solid ore four inches in thickness. The Golconda lode, near Dumont, has been leased to Mr. Tryner, who will commence work right away. We are acquainted with this property and know it to be a number one gold lode. A fair vein of ore has been opened up in the lower east level of the Maple Leaf lode, York district. A tunnel has been started to cut the St. Louis lode, on Capital mountain. The raise which has been under way on the Lyon lode, Fall river, has just been completed, and a contract to drive the drift ahead has been let. The breast shows a vein of solid ore eight inches in thickness. The standard tunnel, on Fall river, has been driven a distance of 85 feet this year. This tunnel has crossed several veins, three of which look very promising. A contract has been let to drive the east drift on No. 6 ahead. The breast of the latter shows a vein of solid copper pyrites, ranging from six to eight inches in thickness. The following Clear Creek mining companies have

paid dividends as follows for the first five months this year: Colorado Central, \$27,500; Friland, \$60,000; Plutus, \$20,000. The Rombauer hydraulic, at Empire, is now in working order and running like a charm under the able management of Amos Morse. W. M. Moore and Silas Hanchett, of Empire, Henry Lehman and Capt. Mills, of Middle Park, and Chas. W. Steele and Armstrong Shepherd, of Georgetown, have associated themselves together for the purpose of testing the so-called carbene fields near Grand Lake. They propose sinking a shaft 60 feet. Martin and Hannigan have resumed work on the Mauch Chunk lode, Columbian Mt., and are driving the drift ahead, which starts in near Beaver gulch. The breast shows a little mineral coming in on the foot wall. This vein produced some rich ore in early days.

IDAHO.

ORE.—Coeur d'Alene Record, June 14: Bob Horn and Chas. Ruddy have bonded the Central mine, on Boulder creek, one mile from Mullen City, and will begin taking out ore at once, and expect to be shipping to the Kentucky Smelting Works at Milo within six weeks. The Central is presumed to rank next to the Hunter in value. The ore is high-grade galena, assaying at the present point of development 40 ounces in silver and 60 per cent lead. The wisdom of the county commissioners in ordering the construction of the Mullen City and Two-Mile road is shown by the fact that in the working of this single property it will keep thousands of dollars within the county which otherwise would have gone out of the territory, as these gentlemen had intended to ship their ore via Thompson Falls to Helena. All the bedrock which was piped off on the Arizona claim has been cleaned and work suspended for the season. This claim has done well, and with a supply of water would make the owners rich in a single season. But like all the old channels it can only be worked a short time in the spring. Most of the money taken out this year has gone for expenses of flume and water pipes and getting the claim well started. From this time on but a small percentage of the value of the gold will be needed for expenses. It has fully met the anticipations of the owners, and adds another proof of the richness of the old channel. The Occident arrastra stopped two hours Tuesday and took out about \$1200 for current expenses, and will run for some time before making a thorough cleanup. We were hoping they would take out the entire produce of their 100-ton run, as several parties are anxious to make this test a basis for determining whether or not to put up similar works. Rich strikes are reported on the Fanny May and Iuka lodes on Elk creek. These properties are owned by Albert Allen, Martin Lewis, of Salt Lake, James Pannel, Maurice Leaby and Hank Otley.

MONTANA.

ANACONDA.—Cor. Butte Miner, June 19: The stamp mill of the Pyrenees Gold Mining Company is now in operation at their mine at Georgetown. Superintendent C. H. Moore arrived in town yesterday with a considerable shipment of bullion, which he took to Butte last evening. Caplice & McCune put a large force of men to work this morning to construct an immense dam for the Anaconda Company, about a mile west of this city.

NEW MEXICO.

SOCORRO.—Bullion, June 19: Robinson and Glasen have resumed work on their gold bonanza in the Oscuras. The Graphite smelter is in receipt this week of a consignment of ore from the Comstock mill of Kingston. On Tuesday last 13 cars of bullion, containing 182 tons in all, left the Socorro depot for the Eastern market. Capt. Day has struck \$60 ore in his Mugwump claim, situated in Water Canyon. He now proposes to increase his working force. George Cross, of the New Mexican, is developing a good-looking claim in the vicinity of Santa Fe. It possesses promising iron croppings. Dr. Shands, of Forney, Texas, and co-owner in the St. Vincent mine, left for his home this week. Work on this property is to be prosecuted with vigor. Wm. Dunn, of Hermosa, arrived at the Biling Works Wednesday with a wagon train loaded with ore from the Antelope mine of that camp. It samples \$400 per ton. Col. E. L. Mann will in a few days resume operations on his Bonanza extension of the Silver Glance, in the Polydoro district. This is one of the highest grade mines in the county. George Voorhies is the owner of a valuable group of claims in the San Acio district, on which he will inaugurate development speedily.

UTAH.

REVIEW.—Salt Lake Tribune, June 18: There has been no event of importance during the week. A cold wave with wind and rain swept over the country, but no frosts are reported in the valleys; snow fell in many places in the hills. The shipments of the metals out from this city for the week ending Saturday, June 12th, inclusive, were as follows: 35 cars bullion, 858,498 pounds; 33 cars ore, 737,218 pounds; five cars copper ore, 150,300 pounds; two cars sulphur, 51,000 pounds—74 cars, 1,797,016 pounds. While shipments of ore were considerable compared with the output for some time past, the ore treated at home continues large in amount and value. For the week ending June 16, inclusive, the amount of it received and held in this valley was \$85,380.47; amount of bullion received at the same time, \$116,813.82, a total of \$202,194.29. For the previous week the receipts were \$217,208.96, of which \$68,952.23 was in ore and \$148,256.73 in bullion. No ore was received from the Ontario during the week. The ore sales for the week were \$26,173.53. The mill started again on the 16th. Two hundred shares of Ontario stock were sold in New York on the 7th and 10th, at \$29@29.50. The Daly product for the week was seven bars of bullion, \$7799.82; ore sales, \$7320.53; total, \$15,120.35. The Horn Silver shipped 20 cars of high-grade ore last week, but no figures can be had of its value. The base bullion received during the week is valued at \$16,700; the fine bars at \$15,600. The Stormont sent up on the 14th, in fine silver, \$2774. The Hanauer smelter produced during the week \$30,030 in bullion, the Germania, twelve cars, \$23,112.13. The Alice sent down on the 14th sixteen bars of bullion, \$13,597.69.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific States.

From the official report of U. S. Patents in Dewey & Co.'s Patent Office Library, 252 Market St., S. F.

FOR WEEK ENDING JUNE 15, 1886.

\$43,624.—CLEANING GRAIN—B. D. Crocker, Walla Walla, W. T.
\$43,891.—APPARATUS FOR CLEANING GRAIN.—B. D. Crocker, Walla Walla, W. T.
\$43,660.—REMEDY FOR DYSPEPSIA—B. Farley, S. F.
\$43,706.—CARTRIDGE LOADER—Geo. J. Foster, Alameda, Cal.
\$43,713.—SAW TOOTH—Simon Kinney, Brownsville, Cal.
\$43,717.—SPRING HARROW—L. A. Manchester, Merced, Cal.
\$43,595.—PRESERVING BEER—T. & D. Morris, S. F.
\$43,596.—SUPPLYING CARBONIC ACID TO BEER IN KEGS—T. & D. Morris, S. F.
\$35,697.—FRUIT DRIER—U. S. Plummer, San Jose, Cal.
\$43,734.—FEED MECHANISM FOR DRILLS—M. Schwarzer, S. F.
\$43,741.—BEER OR FLUID DRIPS—F. C. & H. A. Stober, Sacto, Cal.
\$43,781.—TRANSOM VENTILATOR—J. P. Tierney, Oakland, Cal.

Note.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates and in the shortest possible time.

Mining Share Market.

Mining stocks continue inactive, no developments of special note having occurred of late to enliven matters. The deeper sinking of the Combination shaft on the Comstock has been suspended, the present desired depth having been attained. The shaft is now 3250 feet deep. At the 3200 level a station was commenced yesterday, leaving the 50 feet of the shaft below that point for a sump or drainage well. This station is being opened on the west side of the shaft, and when it is fairly chambered out and completed a lateral drift north will be started from it to meet the drift coming south from the Hale & Norcross deep winze on the same level. It is a very significant circumstance that no increase of water was found in this 100 feet of deeper sinking, and especially at the bottom, where the shaft passed into the main channel. A new base of explorations is now reached and its development commenced. It will take at least a year to thoroughly explore this new level, and it being in new and interesting ground it certainly is to be hoped that the good ore developments found in the levels above it may concentrate into a paying bonanza somewhere at that depth.

Bullion Shipments.

We quote shipments since our last, and shall be pleased to receive further reports:

Oro Grande mill, June 20, \$2000; Holberg & Co., 20, \$1000; Moulton, 14, \$18,400; Alice, 15, \$13,597; Hanauer, 15, \$9300; Stormont, 15, \$2774; Germania, 15, \$7179; Idahoan, 16, \$2200; Germania, 16, \$1800; Hanauer, 18, \$3100; Pascoe, 18, \$2100; Crescent 18, \$4500; Queen of the Hills, 19, \$1700; Hanauer, 19, \$1700; Alice, 20, \$14,011; Germania, 20, \$10,177; Hanauer, 20, \$9080; Pascoe, 20, \$1700; Crescent, 20, \$4350. For the week ending June 20, inclusive, there was shipped out from Salt Lake 34 cars of bullion, 812,394 pounds; 28 cars ore, 587,400 pounds; eight cars copper ore, 243,750 pounds; a total of 70 cars, 1,643,544 pounds. Wells, Fargo & Co., Salt Lake, shipped last week \$81,450; McCormick & Co., \$68,199; Jones & Co., \$38,947; Union National Bank, 20, \$13,597.

New Incorporations.

The following companies have been incorporated and papers filed in the office of the Superior Court, Department 10, San Francisco:

GOLD VALLEY G. M. Co., June 22d. Location, California. Capital stock, \$1,000,000, in 100,000 shares. Directors, Guy Thorp, W. B. Helling, A. Judson, George K. True and W. R. Judson.
OWYHEE M. Co., June 22d. Location, Nevada. Capital stock, \$1,000,000. Directors, J. C. Eaton, E. Scott, J. W. Pew, A. L. Perkins and W. C. Price.

INDEPENDENT AUTOMATIC PORTABLE GAS CO., June 22d. Capital stock, \$100,000. Directors, J. C. Merrill, T. N. Wand, J. I. Ayres, A. S. Bell and Edward Webb.

DYNAMITE SHELL CO., June 23. Object, to operate and develop a patent method or art of preparing and charging projectiles with dynamite, and to engage in tunneling, mining and other blasting operations. Directors, J. W. Graydn, J. G. de Staack, Charles Webb Howard, Julius Bandmann and Frank Roller. Capital stock, \$10,000,000, divided into 100,000 shares.

Take a Receipt.

ALWAYS TAKE A RECEIPT from a newspaper agent. Not simply because a few out of many are tricky or careless, but because accidents will sometimes happen to the best of business men. It is a favor due to the publisher that every subscriber shall take a receipt from the agent, or clerk whom they pay. All our receipts have a corresponding stub which agents are accountable for and are required to return.

The Labor Problem.

By far the most momentous question before the country at this time is that which involves the relations of labor to capital. It overtops all other questions. In almost every department of industry, and in all sections of the country, there are demonstrations of organized united strength and firmness of purpose designed to benefit the laborer. The movement made a forcible demonstration of its strength by precipitating its earliest efforts upon two of the strongest, most extensive and best organized classes of corporations in the country—an overhead railroad at St. Louis and a city elevated railroad in New York. Demonstrations of this class have sometimes been called "a war of labor against capital." But such is a misnomer so far as the real issue is concerned. It is true that a certain element of our population often takes advantage of labor troubles to introduce a foreign element into the controversy, the movers in which are made up of a set of vicious individuals who openly profess to make war against capital; but that element has no place in the present controversy and has been most emphatically repudiated. Its presence, wherever it appears, is an insult to honest labor. But it is true that

There are Differences of Opinion

Among workingmen, as to how far their demands should go. No reasonable, thinking worker will ask for anything more than a fair living return for his labor—such pay as will enable him to support his family in a manner worthy of an American workingman. The same fairness will accord a reasonable return for the investment of his employer. Every intelligent workingman recognizes the unwritten but infallible law, that by reason of difference in intelligence, shrewdness and industry there must, and always will be, an unequal distribution of property; but the same road for improvement is open to all alike. But, unfortunately, all are not thus considerate, and demands have been made in some quarters which were altogether unreasonable, and which have consequently utterly failed. Two notable instances of this kind are the strikes on the Missouri Pacific at St. Louis and on the Third Avenue in New York. The number of workingmen actively engaged in this movement throughout the country is comparatively small, not amounting to 10 per cent of the total of those engaged in the various trades represented, and that, too, leaving entirely out of the question those engaged in agriculture, a number larger than all the trades combined. The members of the confederated trade unions are in such a small minority that they can have no hope to succeed in any important measure, except they have the sympathy of the working people at large. With that advantage they will be able to carry out every reasonable measure which they may initiate. Hence, due care and deliberation should be given to their every act. There are

Evils of Unquestioned Existence

Which must be rectified, and by which the workingmen may be benefited in various ways without any serious detriment to employers. Let the real evils be eradicated, but let that be done in a way least calculated to work injury to the innocent. Many of the strikes which have been ordered have worked incalculable injury to other workmen not directly interested. Such strikes have clogged the wheels of commerce and seriously discouraged the great army of the innocent workers who have had nothing to do with the troubles complained of. The great majority of workers have had no sympathy with such movements, and they have ignominiously failed. A few more repetitions of similar mistakes will turn public sympathy entirely from agitators, and all their efforts will come to naught. By all means, the workingmen should

Beware of Mistakes.

Better suffer a little longer and secure the sympathy without which they cannot hope to succeed. We have too much confidence in the good judgment of the laboring classes in this country to believe that they will, upon due reflection, sacrifice their individual judgment and conscience to a few unscrupulous men, whose only aim is notoriety. Do not be led into false positions—into irremediable mistakes. Have due regard to the rights of others while considering those of your own. There is quite too

much vicious preaching of designing men prominent in labor societies in insisting that the average capitalist is a grasping, soulless person, disregarding of the rights and needs of his employees. There are indeed many instances of that kind, but as a rule the assertion cannot be sustained, and its constant reiteration is designed only to appeal to the baser passions, for the still baser purpose of individual notoriety or aggrandizement. Let all such brawlers be classed with the disowned anarchist, for it is from such that the anarchist ranks are recruited.

The Mistakes in Striking.

Men have an undoubted right to refuse work—strike if they will—but no body of strikers has any right to physically interfere with another who is willing and anxious to work and needs work. The moment this "right of liberty and the pursuit of happiness" is interfered with or the property and lives of his employers assailed and destroyed, that moment the striker has crossed the line which separates him from the sympathy of his orderly fellow-workmen and the public at large. He is then no better than the armed Ku Klux or destroying anarchist. The American people are patient and long-suffering, but they will not tamely submit to any very long continuance of such outrages. Moreover, when the day of trial comes no distinction will be made between such actual law-breakers and those who stand back and support them through secret or any other organizations.

Legitimate Striking and Boycotting.

There is such a thing as allowable and legitimate striking and boycotting. The line which limits their legal action is so plainly drawn that it must be apparent to every well-disposed, right-thinking person. Every man has a right to sell goods or his labor to any other man who is willing to buy or employ. He may "strike" if he chooses, and withhold his labor; that is merely the refusal of a bargain with which he is displeased. He may "boycott" if he chooses, which is merely a refusal to hold intercourse or dealings with his objectionable neighbor. He may concert to do either with others, and so far as he avoids forcible interference with the rights of others who think differently from him, and confines his efforts to argument and moral suasion, he remains under the protection of the law. But he has no right to forcibly prevent another from exercising the same rights of free agency of which he claims the privilege. The country will not tolerate outrage and violence, for that is anarchism. There are now something like 100 men under arrest for acts of violence as strikers or boycotters. If such acts are continued, they and all others who may follow in their footsteps may expect to suffer the most rigid penalties of the law. But if the present season of cessation of such violence should continue and bid fair to become permanent, the fullest amenities of the law will be held out, under the view that the recent infractions were inconsiderate and due to an unhealthy excitement, mainly brought about by anarchists and enemies of law and order. The lesson taught by recent events is that the law must be held supreme at all hazards, and the verdict will be indorsed by nineteen-twentieths of our entire population.

Three Methods With Labor.

It has been truly said that there are three methods with labor. The first is an old-time one, and now, as we hope, somewhat obsolete. It is to get as much as possible out of the workmen and give the least possible return.

The second is more humane and politic. It is to pay decent wages and submit all differences to arbitration.

The third and best is to lend a helping hand and give the workmen, in addition to the mere wages, some share or advantage from the profits of the business.

It seems to us that this last method of dealing with the workman is not only the fairest but the one best adapted to prevent strikes and riots.

We have neither time nor space to discuss these questions to-day, but hope to make further reference to them at some future time. For the present it will be sufficient to quote the language of another, who at a late public labor meeting in Chicago advised "intelligent discussion, correct information, wise counsel, general forbearance on all sides, honest, fair and just dealings between man and man, and a careful

recognition of the rights of all." Such suggestions would, of course, be lost on the unintelligent, hot-headed agitators of labor reform; but we believe they will be justly weighed and considered by the more temperate and thoughtful of the members of trades' unions all over the country.

Books on Working Ores.

By GUIDO KUSTEL, M. E.

CONCENTRATION OF ORES (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arc-furnaces, and Gold and Silver Ores generally, with 120 Lithographic Diagrams.

This work is unequalled by any other published embracing the subjects treated. Its author is highly esteemed and read by its readers; containing, as it does, much essential information to the Miner, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in single order. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. Now out of print. Very rare. A few orders only can be filled at \$10 per copy. Sold by Dewey & Co., Publishers, 252 Market St., San Francisco, Cal.

ROASTING OF GOLD AND SILVER ORES (Second Edition) and the Extraction of their Respective Metals without Quicksilver. By GUIDO KUSTEL, M. E. 1880.

This rare book on the treatment of gold and silver ore without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and the why and wherefore. It contains 156 pages, embracing illustrations of furnaces, supplements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. Price, \$3, coin, postage free. Sold by Dewey & Co., Publishers, 252 Market St., San Francisco, Cal.

By C. H. AARON.

AARON'S LEACHING GOLD AND SILVER ORES, the most complete hand-book on the subject extant; 164 pages octavo. Illustrated by 12 lithographic engravings and four wood cuts. Fully indexed. Plainly written for practical men. In cloth, \$3. Sold by Dewey & Co., S. F.

Practical Hydraulics.

By P. M. RANDALL.

A Book for Civil Engineers, Miners, Millmen, Hydraulicians, Mining Engineers, and Irrigators.

This new work is by one of the most experienced hydraulicians of the country. It abounds with useful tables for ready reference, in which the results of abstruse calculations are all placed in a form so that one can find what he wants in a moment. For the engineer the principles, formulae, coefficients, etc., are given; and for those not familiar with higher mathematics, examples, rules, and tables are prepared. Thus the needs of the scientist and the practical miner or millman are each met. It is the most complete work on the subject yet published, and is specially applicable to the Pacific Coast.

Table of Contents.

The following brief abstract of the contents will give an idea of the branches of the subject treated: General Plan; Discussion of the Principles of Hydraulics; Rules Deduced from Formulae Obtained; Examples and Calculations; Extensive Tables for Ready Reference; Fundamental Laws of Hydraulics Demonstrated, and Expressed in Formulae and Rules; Flow of Water through Openings; Weir Coefficients; Triangular Weirs; Flow of Water over Quadrant Weir (tabulated); Application of Tables; Submerged Orifices; Flow through Orifices in Thin Partitions; Tables and Applications; Miners' Inches; Tables and Calculations; Flow of Water through Short Tubes and Compound Tubes; Flow of Water through Pipes; Tables of Velocities and Cubic Feet Flow for Given Fall per Mile and Diameter of Pipe; Coefficient for Bend-Circular and Angular; Flow through Nozzles; Inverted Siphons; Flow of Water in Open Channels; Extensive Tables; Rough and Ready Notes; Hints for Speedy and Approximate Estimates, etc.

Price, \$2.00, post-paid. Sold by Dewey & Co., Publishers, 252 Market St., San Francisco.

Practical Treatise on Hydraulic Mining

By AUG. J. BOWIE, JR.

This new and important book is on the use and construction of Ditches, Flumes, Dams, Pipes, Flow of Water on Heavy Grades, methods of mining shallow and deep placers, history and development of mines, records of gold washing, mechanical appliances, such as nozzles, hurdy-gurdys, rockers, undercurrents, etc.; also describes methods of blasting; tunnels and sluices; tailings and dump; duty of miners' inch, etc. A very practical work for gold miners and users of water. Price, \$5, post-paid. For sale by DEWEY & CO., Publishers, 252 Market St., San Francisco.

An Easy Binder.

A. T. Dewey's patent elastic binder, for periodicals, music and other printed sheets, is the handiest, and very cheapest of all economical and practical file binders. Newspapers are quickly placed in it (as received) and held neatly, as in a cloth-bound book. It is durable, and so simple a child can use it. Price (size of this paper, Harper's Weekly, and Scientific American), 75 cents; postage 10 cents. Postpaid to subscribers of this paper, 50 cents. For sale at this office. Send for illustrated circular. Agents wanted.

Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, or beyond the time he intends to pay for it, let him not fail to write us direct to stop it. A postal card (costing one cent only) will suffice. We will not knowingly send the paper to anyone who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or some irresponsible party requested to stop it, we shall positively demand payment for the time it is sent. LOOK CAREFULLY AT THE LABEL ON YOUR PAPER.

Joshua Rose's Great Treatise on Steam Engines.

JUST PUBLISHED.

Modern Steam Engines.

An Elementary Treatise upon the Steam Engine, written in Plain Language, for use in the Workshop as well as in the Drawing Office; giving full explanations of the Construction of Modern Steam Engines; including Diagrams showing their actual Operation; together with Complete but Simple Explanations of the Operations of Various Kinds of Valves; Valve Motions, Link Motions, etc., thereby enabling the Ordinary Engineer to clearly understand the Principles Involved in their Construction and Use, and to Plot Out their Movements upon the Drawing Board. By JOSHUA ROSE, M. E., author of "The Complete Practical Machinist." Illustrated by 422 engravings. In one volume, 4to., 320 pages. Price, \$6.00, free of postage to any address in the World.

An Illustrated Circular, 8 pages, 4to., giving the Contents of this remarkable book, will be sent free to any one who will furnish his address.

\$1,000 CHALLENGE!

**THE FRUE ORE CONCENTRATOR,
OR VANNING MACHINE.**

PRICE: FIVE HUNDRED AND SEVENTY-FIVE DOLLARS.
(\\$575 00), F. O. B.

OVER 1,000 ARE NOW IN USE. Saves from 40 to 100 per cent more than any other Concentrator. Concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order and ready to make tests at the Fulton Iron Works, No. 220 Fremont Street, San Francisco.

As the result of a suit East against an End-Shake Machine (the Embrey), similar to the Triumph, the Frue Vanning Machine Company owns the Embrey patent, and can put in the market an End-Shake Machine of earlier patent that will do as good work as the Triumph, and superior in construction and durability. There will be no risk of suit for infringement.

The Frue Vanning Machine Company warn the public that they claim and will prove the Triumph machine to be an infringement patents owned by them.

Protected by patents May 4, 1869, Dec. 22 1874, Sept. 2, 1879, April 27, 1880, March 22, 1881, Feb. 20, 1883, Sept. 18, 1883. Patents applied for.

N. B.—We are and have been ready at any time to make a competitive trial against the Triumph, or any other Concentrator for stakes of \$1,000.

JAMES F. HOUGH, General Manager of San Francisco and Portland, Or., Branches 15 and 17 FIRST ST., near Market, SAN FRANCISCO, CAL.

JENKINS PATENT VALVES.

Gate, Globe, Angle, Check and Safety.

Manufactured of BEST STEAM METAL. We claim the following advantages over all other Valves and Gauge Cocks now in use:

1. A perfectly tight Valve under any and all pressures of steam, oils or gases.
2. Sand or grit of any kind will not injure the seat.
3. You do not have to take them off to repair them.
4. They can be repaired by any mechanic in a few minutes.
5. The elasticity of the Disc allows it to adapt itself to an imperfect surface.

In Valves having ground or metal seats, should sand or grit get upon the seat it is impossible to make them tight except by regrounding, which is expensive if done by hand, and if done by machine soon wears out the valve, and in most cases they have to be disconnected from the pipes, often costing more than a new valve. The JENKINS Disc used in these Valves is manufactured under our 1880 Patent, and will stand 200 lbs. steam. Sample orders solicited. To avoid imposition, see that Valves are stamped "Jenkins Bros." For sale by

DUNHAM, CARRIGAN & CO., San Francisco, Cal.

THE FRISBEE-LUCOP MILL,

A CENTRIFUGAL ROLLER MILL

—FOR WET OR DRY—

Reduction of Ores, Quartz, Phosphate Rock, Carbon, or other Mineral Substance to any degree of fineness in a rapid and economical manner.

Any method of amalgamation may be applied.

At 300 revolutions per minute will pulverize 2000 pounds of quartz per hour to 60 mesh dry, and from 3000 to 6000 pounds wet.

All wearing parts easily and cheaply replaced. May be seen in operation at the New York Metallurgical Works, 104 and 106 Washington St., and Pacific Iron Works, San Francisco.

Certificates as to performance of the Mills, and any information required, furnished on application.

1885.

RANKIN, BRAYTON & CO.,
BUILDERS OF...
MINING MACHINERY.

San Francisco: 127 First Street. Chicago: 100 N. Clinton. New York: 145 Broadway.

PLANTS FOR GOLD AND SILVER MILLS, embracing machinery of LATEST DESIGN and MOST IMPROVED construction. We offer our customers the BEST RESULTS OF 35 YEARS' EXPERIENCE in this SPECIAL LINE of work, and are PREPARED to furnish from SAN FRANCISCO or CHICAGO, the MOST APPROVED character of MINING AND REDUCTION MACHINERY, adapted to all grades of ores and SUPERIOR to that of any other make, at the LOWEST POSSIBLE PRICES.

We are also prepared to CONSTRUCT and DELIVER in COMPLETE RUNNING ORDER, in any locality, MILLS, CONCENTRATION WORKS, WATER JACKET SMELTING FURNACES, HOISTING WORKS, PUMPING MACHINERY, ETC., ETC., of any DESIRED CAPACITY.

WATER JACKET SMELTING FURNACES

For COPPER and ARGENTIFEROUS LEAD ores of NEW and ORIGINAL DESIGNS, covered by LETTERS PATENT. No other Furnace CAN COMPARE with these for DURABILITY, and in CAPACITY for uninterrupted work. MORE THAN 150 of them are now RUNNING in various parts of THIS COUNTRY, as well as many in FOREIGN COUNTRIES, giving results NEVER BEFORE ATTAINED as regards CONTINUOUS running, ECONOMY of fuel, A MOUNT and QUALITY of BULLION produced. These CLAIMS have been PROVEN BY RESULTS in ANY NUMBER of INSTANCES, and the GREAT SUPERIORITY of this SYSTEM of smelting ores DEMONSTRATED BEYOND QUESTION. COMPLETE PLANTS furnished to order of any CAPACITY, with ALL IMPROVEMENTS that experience has DEMONSTRATED as VALUABLE in this class of work.

Beyond question the cheapest and most effective machine of the kind now in use adapted to all grades and classes of ores.

This machine has been THOROUGHLY TESTED for the past TWO YEARS, under a GREAT VARIETY of CONDITIONS, giving most EXTRAORDINARY results FAR IN ADVANCE of anything EVER BEFORE REALIZED. A recent COMPETITIVE TEST at the Carlisle Mine in Mexico, showed an ADVANTAGE OF OVER 30 PER CENT in favor of THE DUNCAN. The amount SAVED OVER THE TRUE being sufficient to PAY THE ENTIRE COST of the machines EVERY MONTH of the YEAR. One of its MOST VALUABLE features is as an AMALGAMATOR. It saves all THE AMALGAM GOLD and SILVER that ESCAPES THE BATTERIES, PANS or SETTLERS, making the machine worth MORE than ITS COST for THIS PURPOSE ALONE.

Baker's Mining Horse Power.

Possessing all the requirements of a first-class hoist and affording means for the continuous operation of a Pump or Blower, without interfering with a hoisting apparatus. It is made entirely of iron, no piece weighs over 300 pounds. At the ordinary speed of a horse, a 1,000-pound bucket of ore may be raised 120 feet per minute. The hoisting-drum is under the complete control of the man of the shaft, and is capable of carrying 500 feet of five-eighths steel rope. SEND FOR CIRCULAR.

**ADAMANTINE Shoes, Dies and Crusher Plates**

We manufacture the above Adamantine Shoes, Dies and Crusher Plates. They are in use on the hardest quartz in the United States and South and Central America, and have been

for the last ten years; we warrant them to out-wear three (3) sets made of any other metal, and many report that they last from 4 to 8 times longer than any other make. They never break AT THE SHANK, and the wear is so light that little or no foreign matter gets mixed with the crushed ore.

Also CHROME CAST STEEL for Mining and General Use, of the finest quality. For further particulars, address

...SOLE MANUFACTURERS OF...

KENDALL'S PATENT
QUARTZ MILLS.

Having renewed our contract on more advantageous terms with Mr. S. Kendall for the manufacture of his Patent Quartz Mill, we are now enabled to offer these mills at GREATLY REDUCED PRICES. Having made and sold these mills for the past five years, we know their merits, and know that they have given perfect satisfaction to purchasers, as numbers of commendatory testimonials prove. We feel confident, therefore, that at the prices we are now prepared to offer them, there is placed within the reach of all a light, cheap, and durable mill that will do all that is claimed for it and give entire satisfaction.

CALIFORNIA

ARTIFICIAL STONE PAVING CO.

(SCHILLINGER'S PATENT.)

—FOR—

SIDEWALKS, GARDEN WALKS, CORRIDORS, OFFICES, CARRIAGE
DRIVES, STABLES and CELLAR FLOORS, KITCHENS, Etc.

The Courts here and in the East have decided that Artificial Stone Pavements with plastic concrete and in detached blocks, are infringements on the Schillinger Patent; and also, that when the plastic material is blocked off with a trowel and cut through far enough to control the cracking caused by shrinkage, that such pavement is in law the same as if laid in detached blocks, and is an infringement of the patent. All property-owners having such pavements laid without the license of the above Company, will be prosecuted.

HERCULES SLAYING THE GIANTS.

HERCULES POWDER

Derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

No. 1 (XX) is the Strongest Explosive Known.
No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE

THE CALIFORNIA POWDER WORKS,

THE GIANT POWDER COMPANY

Manufacture Three Kinds of Powder, which are acknowledged by all the Great Chemists of the World as

The Safest and Strongest High Explosives in the Market.

GIANT POWDER or DYNAMITE,
Of Different Strengths as Required.

NOBEL'S EXPLOSIVE GELATINE, which contains 94 per cent of Nitro-Glycerine, and GELATINE-DYNAMITE, Stronger than Dynamite and even Safer in Handling.

JUDSON POWDER IMPROVED.

FOR RAILROADS AND LAND CLEARING. Is from three to four times stronger than ordinary Blast ing Powder, and is used by all the Railroads and Gravel Claims, as it breaks more ground, pulverizes better and saves time and money. It is as dry as the ordinary Blasting Powder and runs as freely.

Dewey & Co.'s Scientific Press Patent Agency:

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most reliable advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free.

HOOD'S FOUNDRY COKE.

Consumers are respectfully informed that owing to inferior brands of Coke having been sold in this and other countries under the name of "Patent Coke," the Glamorgan Coal Co. (Limited), Cardiff, in May, 1884, abandoned the title of "Patent Foundry Coke," substituting that of "Hood's Foundry Coke."

This Coke is exclusively used by the Selby Smelting and Lead Co., Union Iron Works, Professor Thomas Price, and other consumers here. Large quantities are regularly forwarded to Copper Smelters in Arizona and New Mexico, and also to consumers in Nevada and Salt Lake.

The undersigned are the SOLE IMPORTERS of the above Coke, which is for sale in quantities to suit purchasers.

IMPORTANT TO GOLD MINERS! SILVER-PLATED AMALGAMATING PLATES FOR SAVING GOLD

IN QUARTZ, GRAVEL AND PLACER MINING.

Warranted the Best Made, Durable and Satisfactory. Full weight of silver and best quality of plating guaranteed.

BEST SOFT LAKE SUPERIOR COPPER USED.

3000 Orders filled. Referencee first class. Prices the very lowest. Have received every Medal awarded on the Pacific Coast for Mining Plates. Old Mining Platee Bought, Replated, or Gold Separated.

SAN FRANCISCO GOLD, SILVER and NICKEL PLATING WORKS, 653 & 655 Mission St., San Francisco.

E. G. DENNISTON, Proprietor.

These Plates can also be procured of JOHN TAYLOR & CO., Dealers in Assayers' and Mining Material, 112 to 118 Pine St.

NOTICE.—Mining men are cautioned against purchasing inferior quality of Silver-Plated Mining Plates now being manufactured in this city. There has been a general complaint by purchasers that these plates proved defective in plating and short in weight of silver, assays showing great deficiency in silver guaranteed. Thin, light plating looks the same as heavy, but has no durability. Good plates can be furnished at same price these poor plates cost.
